>lead to be beneficial.

Adding to Reg's good advice...

A number of people have done the same with a stack of 6-7 2in ferrite rings, and it seems to work well. The single mains feed to *all* the radio gear goes through this choke - with British mains wiring, that is three wires: live, neutral and safety ground.

The reason for using so many ferrite rings is that there's a limit to the number of turns of triple heavy mains wire that you can wind on a 2in core. Therefore you need either bigger cores or more of them in a stack (superglued together). Another way of getting a big chunk of suitable ferrite is to use the core from a scrapped TV deflection yoke - apparently about 10 turns is good for HF. It's not pretty, but at least it's free.

The choke prevents RF from either entering or leaving the radio gear via the mains wiring. It does not affect the mains safety ground connection, but it means that the mains ground is not trying to act as your RF ground as well.

It's generally better not to attempt an RF ground connection from the shack, especially not if it's upstairs. Balanced antennas don't need an RF ground, and attempting to provide one may make the RFI situation worse. For antennas that do need an RF ground, it should be right out there at the antenna.

>At least it makes one feel more relaxed until the XYL's vaccuum cleaner
>is switched on!
>
Nothing cures that - especially when it's being used right outside the shack door, as a form of heavy hint!

Hi All:

I believe that it's clear from reviews and adds for the antenna that its a
center loaded (coil) link coupled,with bandswithching taps for changing
bands, vertical dipole.
The efficiency of the antenna is strongly effected by the Q of the loading
coils. The capacitive end loading from the "T" bars reduce the size of the
coil need to resonate the antenna there by lowering losses.
I modeled the 80m version, and it's down in gain (I can't remember how much
right now, I'm at work) from a full size vertical, (surprise surprise) but
much better at the low angles for dx than my low (40') dipole.
And with much reduced response to high angle signals it would reduce the
signal strength of local stations increasing the signal to interference
level. Coupled with not benefiting from radials it's an attractive antenna.
It still suffers from the ground loss in the far field that all vertical
over imperfect ground suffer though.

I have spent months using NEC Win Plus (NEC2) to come up with a 4 element Yagi to fit my needs. I mostly use free space to start out tweaking. Ok - Now I have that "perfect" pattern with deep back corner nulls - but when I actually build this antenna and mount it up on the roof have I wasted my time? Should I be using the "Real Ground" or some other (non free space) option to make sure I get the rear pattern I want when I actually build the antenna?

Thanks!

Scott.

> dipole.

David,
Very good. Ofcourse we first have to decide whether we have "our
house in order" If not we try to pursue a better more uniform way.
The latest antenna is the IR antenna which is a measurable advance
over others.
It reference to gain was what was actualy measured and I like that
real term.
It then was able to talk of gain that referred to the WHOLE band and
I like that. Can we improve on this good method of reporting the
measure of the product, and this is what I focussed on.
So the multi bander offered was a single element that could reflect a
dipole
in many ways until it reached the 1/2 wave point, after which the rest
is dormant and any extension beyond that just adds to turning radius.
Ofcourse all tribander forms do this because of traps. So tho the
tribander has the same gain as a dipole the penalty is that it is
twice as long (using 10
metres as a standard) so I thought that they don't have the same order
of merit.
If a new design came along where say the IR element continued to
increase gain
by continueing the the element travel to equal its turning radius I
would consider that as an increase in merit but then the cry would
really come along
by detractors that Hey, it is twice as long ! Where as I say if he has
to have that turning radius then more power to him for using it all to
radiate.
In my case when I did this by using the whole turning radius to form
in phase
radiation plus removal of the less efficient ends ala of the radiation
pattern ala capacity hat, there was uproar when gain was mentioned
So now we have a problem in some ways, when an element uses all
its
physical length to radiate in an additive way similar to the Zepp
aproach
only constricted to a single half wave or less, or more, produces
collinear
radiation form ? If such a design is not accepted as giving more gain
than a dipole (see archives) How should we give it some order of merit
when
theIR designers introduce the same with their designs ! The design is
now
established so how are we going to rate it if this august group
rejects the
norm.
regards

Art

If the antenna is mounted 3/4 or more waves above ground, the general azimuthal pattern will be correct. Of course, you now have an antenna with a launch angle which is not at the horizon (such as you get with free space), and certainly has no response at negative elevation angles.

I suspect that if you tweak the sim with real ground, you will find you already did pretty well from free space, and its probably not worth re-doing. At worst, your SWR will be off slightly (doubt moderately) and the F/B will not prove quite as deep.

Here's an easier way. Use a resonant 20m dipole and feed it with
an integral number of 1/2 wavelengths of ladder-line. No tuner
needed. Add a quarter-wave transformer (7.8') of ladder-line when
you want to use the 20m dipole on 10m. No tuner needed.

a full size dipole is 2.35 dBi isn't it ? hmmm
What's the "gain" when it is "on the ground" mounted 2 ft up ?

I can see that design turn into a nice antenna construction project .
And it is portable ... and seem easy to set up .. I see the usefulness
while camping or during the IOTA contest .. as I had to use trees this
summer to get a dipole up .

How about a wire version ? If I get one of those German pull up
fiberglass mast (32 ft?), then stretch 2 top wires 12 Ga of 7 ft
attached to guy wires on each side 50 ft away, 2 bottom wires also ?
Would the dimensions of 16 ft in the middle stay the same, and using
the cap of 200 pF in series also ?

According to the QST review, it has five loading coils at the dipole feedpoint,
and energized relays activate different sets of coils on each side of the feed
point, controlled by a bandswitch in the shack.

Sounds a little complicated -- there may be some way to simplify in a homebrew
version.

Anyone help with stacking halos (folded dipoles bent into a near circle)?
Phasing? spacing? What I'd like to build is a horizontally polarised
omnidirectional antenna with moderate gain. For 2 metres 144 - 146
(later possibly for 6 m).

Intuitively I feel that stacking halos should squeeze
the donut down toward the horizon but I've not found
any examples on the web so I have this sinking feeling
that there must be something obvious I'm missing.

Any pointers would be much appreciated.

vy 73 and TIA

Reg has a program the works pretty well for that. It's at
http://www.btinternet.com/~g4fgq.regp/page3.html
The program for small receive loops is rjeloop3
You can build small loops for SW use, but there may be a limit to how
high a frequency, due to the stray capacitance in the windings. I
built a few of them just testing them out. I settled on a round 16
inch loop with about 12 turns as my "everyday" MW loop. It worked out
just about right for my uses. Covers from 500-2000 kc with the cap I
am using. Works well for MW, and also can use it for 160m at the upper
end of it's range.

Dear Henrik,

I use an SGC 230 which feeds a 102' wire, centre fed with 28' or so of home brewed 600 ohm ladder. No relation to the G5RV ;-). It tunes fine on all bands including 160 m. I recon that, taking the Q of the pretty crappy inductors in the 230 as 100 (I'm being a little generous there I think) the efficiency on top band is roughly 30 - 35%. I'm restricted by my licence to 10 W at the aerial feed point so I limit myself to 25 W into the SGC. I get good reports. I've had 57 and 58 reports from western Russia and Lithuania and usually get 59 from the U.K. under reasonable condx.

I have choke baluns made with 1' x 10 turn coils in both the feed to the SGC and the control cable. The antenna is roughly 0.2 lambda overall on top band.

Any shorter and the efficiency really starts to plummet as the reactance climbs and the radiation resistance falls off. There really isn't too much room inside the SGC to get higher quality coils in. Be aware that the rest of the power is being dissipated in the coils, so overheating may be a problem if you approach the rated power of the unit. Most of us are forced to use fairly

short aerials on low bands and radiated power is often quite low.

Hi Stephan,

Wire models would work just as well, whatever support system you
provide. Given the original employed 3/4" components and you describe
interest using 12ga wire - there will be some difference. Don't stray
from the geometry. Aside from that, everything should be the same
(ï¿½3dB).

That was NOT a 200pf cap I described:
>>Again, using EZNEC, I added a -200 Ohm load near the source feed
C = 1 / (2 * pi * f * Xc)

You may also wish to simply substitute a popular air variable cap and adjust to discover the actual, in-place value. If this is to be a wire antenna, and temporary at that, you may just wish to keep it a variable cap.

The Hindenburg did not "blow up", it burned. It would have burned
had it been helium, because it was the envelope burning before the
gas caught fire.

Yes. Wind a couple of turns on the core (each pass through the hole of a toroid equals one turn) and measure the impedance over the range of frequencies of interest. (The impedance is proportional to the square of the number of turns.) What you strive for in a wideband transformer is to have the winding impedance be much higher (a factor of 5 - 10 is a generally good working number) than the impedance connected to the winding, so in general, the higher the impedance you measure, the better.

Let's see, if you had a winding to be connected to a 50 ohm impedance, you'd want about 500 ohms. To get that with 5-10 turns would require an impedance per turn squared of 5 - 20 ohms, or 20 - 80 ohms for two turns. Low frequency ferrites provide a relatively high impedance over a very wide frequency range. (See the Fair-Rite web site for graphs.) The impedance you get with low frequency ferrites is essentially resistive over most of the HF range, and it doesn't vary a great deal with frequency, which is ideal for wideband transformer applications. By contrast, high frequency ferrites provide an impedance that's primarily reactive, which is ok, but you don't get as much impedance. By the time you wind enough turns to get the high impedance you need, you might end up above self-resonance where the impedance is lower.

The only exception is if you're dealing with a lot of power. In that case, the low frequency cores can heat due to simple resistive loss (which is often mistaken for saturation), even if the loss is completely insignificant in terms of dB. Then, you're stuck with using a higher frequency ferrite. Type 43 is often a good compromise between impedance and loss -- its resistance equals its reactance in the middle of the HF band.

Low frequency ferrites are obviously not suitable for use as inductors at HF. For most amateur applications, powdered iron is better than even high frequency ferrites for HF inductor applications.

After you model the antenna in free space and tweak it, then model it over ground. You'll find that the strength of the rear lobe depends on the elevation angle. If there's one particular angle or range of angles where you need especially high front/back, you might be able to tweak a little more to get the smallest radiation from the rear at that angle.

But nulls are a lot tougher to accomplish in practice than gain or forward pattern. The reason is that nulls are brought about by subtracting a number of large fields to get a result near zero. Even a slight percentage disturbance in any of the large fields has a big effect on the nulls, while its effect on gain or forward pattern will be minimal. So nulls also suffer from environmental factors such as nearby conductors, slight asymettry in the antenna, and so forth. In practice, you might not see quite as much front/back as the program predicts, no matter how much you tweak the model. So it's worthwhile to get a good front/back ratio on the model, but probably not worthwhile to spend hours squeezing the last few dB out of it.

This gives you the ease-of-driving-it, certainly, and eliminates the
trap losses.

I don't see that it gives you any directional gain (compared to a
standard dipole), which seems to be part of what Art was trying to
accomplish.

Scott, I always use real ground and height because it is realistic and
you can measure its parameters. If you use real space you cannot
measure it when you have installed you antenna and,more important of
all, the free space
form of design cannot duplicate what one sees in the real world,
especialy the true pattern. This is not to say that measurements in
outer space do not have any use especially for true mathmaticians or
other scientific people including those 'aliens', but the average ham
wants to use his antenna on this earth, talking to people on this
earth and to get maximumum efficiency from the area he has chosen for
himself and to measure it in the event of conflicts.

>extremely similar to the "Lazy H '. Can't such an array
>be made directive with a good front to back i.e. all
>radiation being additive ?

If you put the second (phased) collinear off to one side, you'll get more
directional gain in both forwards and backwards direction... but the
"turning radius" for the array will be huge (maybe 4x the turning
radius of a single collinear). And, because the arrangement is
symmetric, you'll have a F/B ratio of 0 dB.

If you put one of the collinears 1 wavelength "in front" of the other,
and size/tune/phase them identically, you'll end up with a narrower
beamwidth... but, again, you'll have a huge turning radius and no
forward-to-backward selectivity.

Best approach would be to put one a quarter-wavelength ahead of the
other and add a quarter-wavelength phasing line... this would give you
roughly 3 dB (I think) of additional forward gain, and a big deep null
off of the back. Not too shabby, with an increase in turning radius
of only about 6%.

The forward pattern would, I think, not be as "clean" as you'd get
from a Yagi having a similar boom length. You'll end up with a
complex series of lobes and nulls, due to cancellations and
reinforcements between the different quarter-wave radiating sections.
You'll get a similar set of effects off of the back end. Interesting
things might happen to the feedpoint impedance.

And, I'm far from sure how this sort of array would behave if you try
to use it on 15 or 20 meters. If you'd implemented the elements as I
suggested (phasing sections, plus a trap to short them out) you'd end
up with two identical halfwave dipole radiators, separated by somewhat
less than 1/2 wavelength... so it'd provide some modest gain and a few

dB of front-to-back.

The real question, once again, will be whether this sort of array provides more useful gain (and a more useful pattern) on 20 meters than a conventional two-element Yagi with an ordinary half-wave resonant radiator and a single reflector or director. And, how will it compare with a conventional multiband Yagi (e.g. one trapped radiator, and either two reflectors or a single trapped reflector)?

It'd be great if you'd propose a design in sufficient detail (and with unambiguous, industry-standard use of technical terminology) to allow it to be modeled.

Since you have a design in free space that you like, why not try it
over 'real ground' and see what it looks like?

You can also predict what the optimum height will be.

By the way, what band are you talking about?

Hi Dave,

A half wave 20M length 10M radiator has more gain that a half wave 10M length 10M radiator (about 2.4dB). There is certainly no mystery about that (and no recent discovery either).

Cecil provides for a way to match to that mismatch (a 20M size dipole with a 10M drive, or a 17M drive, or a 15M drive, or a 12M drive) that is simple and as lossless as you will find. I am sure there are variations that allow us to build loss back into the picture - Art simply hasn't gotten around to it yet. When he does, it will be to prove his is more "efficient" or easier than Cecil. The problem is that Cecil's idea suffers from lack of Patent Gain (which being good is not as good as the additional 3dB found in Patent Pending Gain so often non-observed in fractals).

Cecil and the rest of us are yet to catch on to the fact that Patented antennas are 3dB superior to wire antennas - until after 17 years when they slowly lose that gain and become normal. ;-)
Hence, Patent Pending antennas are the most sought after because their, uh, virility is artificially enhanced immensely by lawyers and advertising agents.

Your words about those nulls being difficult to achieve is disappointing! A 30dB F/B is great, but it became obvious if I could make these deep ("corner") nulls occur in real life, a little adjustment of the rotor off into the -50dB null, no F/B ratio could match! The environmental factors you mention are definitely going to exist for me - There are some 220V lines that run the length of the attic that will (probably) influence the pattern. I was just hoping that once I built the antenna, I could find that pattern I saw on my design frequency maybe somewhere off to either side, but close!

You mention that it is worthwhile to squeeze a higher F/B ratio out - so does this still apply some what to these "back corner" nulls i've tried to maximize? They are -70dB in free space and -50dB when I model over ground. Jeezzzz, I'd like to keep them!

Thanks!

Scott.

Since I personally have not tried a Hex Beam, I can only go by what is published on Hex Beams site.

Based on what I see our performance should be similar, slightly better in some areas, slightly worse in others. Though, our antenna definitely has the characteristics of a quad in that it is less noisey than a typical beam. Our antenna is a true mini quad and not a Quagi as some other mini quads are.

In short, our antenna performs almost like a full sized quad except in a smaller heavy duty package.

For the applications that I use I would purchase a BBQ. But then again I am a little bias :-).

Check out the comments written about the BBQ10 http://www.degendesigns.com/bbq10_write_up.htm used during Field Day 2002

as
> a capacitor in parallel with the aerial?
=======================

No. It's much the same as a capacitor in shunt with the receiver which is only 50 ohms so it doesn't have much effect.

As I've said before somewhere, the impedance looking into any length of 50-ohm coax terminated with a 50-ohm receiver is exactly the same as looking into a 50-ohm receiver. So the 600-ohm down to 50-ohm mismatch loss is unchanged by the length of coax. That is the direction of signal flow. Get the idea ?

(Incidentally, in a transceiving situation, the only place in the system where (ideally) a conjugate match is intended to exist is at the tuner-receiver junction. Anybody wanna argue ? ;o))

I think it's unlikely that when you build your antenna you'll see 50 or 70 dB nulls where the program says they'll be. You might get lucky and actually get a 50 or 70 dB null at some elevation and azimuth angle or other, but it'll probably be different than the program predicts.

No, I don't think it's worthwhile to spend a much time trying to get a modeled 40 dB null to be 50 or 70. It's time to cut some tubing and see.

Understood - and I do like the elegance of Cecil's approach.

I just wish I could find a really convenient way to switch the
additional balanced feedline sections in and out... my "shack" is a
corner of one bedroom, and there isn't really a convenient indoor
location for the necessary collection of feedline segments. I haven't
been able to figure out a good sort of remote-controlled relay to use
for this purpose, and using a bank of long-strike solenoids to throw
knife switches feels a bit rube-goldbergish.

Larry:
If you have coax and/or rotator cable running up the tower, that will be the radiator. If not, add a piece of RG-8 or something to give you a lower loss conductor than the tower. Bond the shield at top and bottom, and feed the cable instead of the tower.

>
> You don't say where the tuner would be mounted..

Sorry about that but first look at what others have said. One talked
of using ladderline but he neglected to say that finishes up as an
antenna system,
a term he often uses. We then had a variable unductance aproach using
two antennas together with what normally was used as a vertical.
Unfortunately the variable inductances is sittingt right at the point
where maximum radiation occurs which is the last place anyone should
think in deducting length.
As for what I had in mind was what I wrote up in a patent years ago
when I took a rest from my effidiency/length love.
In what I called capacitive coupling I found that one could feed an
unbroken
dipole or vertical by placing in close proximity to it a small dipole
broken at its centre but fed delta fashion. The two dipole lengths
creats a capacitance between them which allows the electrical path to
change naturally , for best matching, this being that the current
wants to flow where there is minimum
resistance.
It sounds complicated but I just used two strips of insulated
aluminium tape
and just pushed the feed and coax inside the vertical to hide its
appearance.
On those experiments I did not add capacity hats at the ends but these
could have been very advantageous. Actually i used a similar
capacitive coupling aproach (capacitive coupling) with all the
elements of a yagi, but that is another story
Regards
Art

Source record: 132119

I took a quick look at how you'd go about making a dual band 20/10 meter antenna that would have more gain on 10 meters than a trap dipole. A typical collinear antenna is 1.5 wavelengths long -- a half wave element in the middle, with a phasing stub at each end, then a half wave of wire beyond each phasing stub -- or longer, with additional stubs and half wave sections. With the 1.5 wavelength arrangement, you can get around 3 dB gain over a half wave dipole. But for the hypothetical dual band antenna, you've only got one wavelength to work with on 10 meters. I fiddled a little with some stubs on a one wavelength antenna, but couldn't do as well as I did with no stubs at all. With no stubs, you've got a plain one wavelength dipole, with gain of about 1.8 dB over a half wave dipole. There's nothing wrong with this, except you've got a very high impedance (thousands of ohms) to match on 10 meters, while on 20 meters the impedance is pretty close to being a good match for coax. For most applications, less than 2 dB wouldn't be worth the hassle.

Art, you said or implied a few postings ago that you could get substantially more gain from a one wavelength dipole (by making the whole wire radiate) than from a half wavelength dipole. Let's take a look at what might be possible.

In "A Critical Study of the Characteristics of Broadcast Antennas as Affected by Antenna Current Distribution" (Proceedings of the I.R.E., January 1936), G.H. Brown investigates the effects of modifying the current distribution on vertical radiators of various heights. Among the current distributions he analyzes are a constant current along the wire. He found that a constant current didn't give any substantial improvement over a sinusoidal distribution (that is, a plain wire with no trickery at all). "It is seen that this antenna [with constant current] must be practically 190 degrees tall to simulate a 190-degree antenna with sinusoidal distribution. Thus this scheme does not appear to be very promising, for it does not seem reasonable to go to all the trouble involved in getting a constant current along the antenna when the same vertical pattern can be obtained by merely using a straight vertical wire antenna of the same height." Then, speaking of all the different current distributions he investigated, he says, "For heights of the order of a half wavelength, it is hard to find anything better than a straight vertical wire."

So Brown wasn't able to come up with much of an improvement over just a straight wire when dealing with half wavelength verticals.

Lincoln La Paz and Geoffrey A. Miller took it one step farther in "Optimum Current Distributions on Vertical Antennas" (Proceedings of the I.R.E., May, 1943), and actually calculated what they determined to be

the best possible theoretical current distributions on wires of various lengths, without regard to how you might be able to achieve them, and calculated the resulting gain. They claim that you can't do better than these optimal distributions no matter what other current distribution you come up with. For a half wavelength vertical, the optimum distribution produces a gain of about 1.6 dB over a plain half wavelength wire (with sinusoidal distribution). So if they're correct, the very best gain you can get from a full wavelength wire (or half wavelength ground mounted vertical), no matter how you fiddle the current distribution, is about 3.6 dB over a half wave dipole (or quarter wave ground mounted vertical). (They show the gain of a half wave vertical to be about 2.0 dB.)

This is a respectable amount of gain over a half wavelength dipole. But how do you get it? They show the current distribution necessary to get this gain as a relatively low current until you get within about an eighth wavelength of the end, then the current increases pretty dramatically. A phase shift occurs about 1/3 of the way up. From a drawing of the distribution, it looks like the current at the antenna tips has to be 5 - 10 times or more the current along 3/4 of the central section. I don't know how you'd achieve a current distribution like this, and wouldn't be surprised if it's not possible. So-called "controlled current distribution" (CCD) antennas, using capacitors inserted at various places along the wire, strive to achieve a constant current along the wire. But as Brown showed, this doesn't give you much gain over a plain wire.

So it looks like a practical limit to the amount of gain you can get by "activating" the outer half of a 20/10 meter trap dipole is around 2 dB, the gain of a plain one wavelength dipole. And to get that, you have to deal with some matching issues. The easiest way to do it is the way thousands of hams now do -- use open wire line and a tuner.

How much gain can *you* can get from a one wavelength wire compared to a half wavelength dipole? If it's substantially more than 2 dB, how much do you get and how do you do it?

I modelled one awhile back...as I recall it was a pretty good performer. A better performer though if you only need one band is the Moxon rectangle with better F/B than the Hex...or than a 2 el Yagi for that matter. I was not able to get a decent model of a multi-band Moxon however.

L.B. Cebik has a comparison on his website that is good reading...http://www.cebik.com/4.html ...as is most of the stuff on his site.

I'm sorry about your problem in not fully understanding the antenna
that I use. But all is not lost. Pretty much every year I bring the
subject up. To do it more than once is not advisable because a lot of
bricks get thrown. Archives will show all the details,someone in this
group also did some modeling after which it was agreed that the
antenna did exactly what I said. Uproar began when I then talked of
gain increase,unfortunately
it was not accepted that this collinear form does not produce the
"normal"
gain which muddied up the waters completely with respect to what
modeling they
did compared to what I use. So to understand the antenna that I use
you will have to read the archives or wait 10 months when I will bring
it up again.
If one of those naysayers opens the door before then and brings the

subject up then all will change. This particular posting was regarding gain and efficiency
if and when such a design not only comes along but also gets accepted by hams
that are familiar with antenna theory. There is the other side where some are not interested in theory .
This is understandable because it is outside of their understanding but it also brings to the fore raucous comments that one can also here on 80 metres......
sssooooooo once a year is enough.

Best regards
Art

Reg, G4FGQ wrote:
"Incidentally, in a tranceiving situation, the only place in the system where (ideally) a conjugate match is intended to exist is at the tuner-receiver jubction."

Reg is seemingly bored with the paucity of contention, so he`s sought some. I`ll take the bait.

Reg sweetened the pot with "ideally".

OK. Ideally, some will seek maximum power output from their transmitters. Some others have differing ideals which don`t demand the maximum.

Maximum output requires a conjugate match. That`s a natural law. A conjugate match does not require a 50-50 split between transmitter internal dissipation and power delivered to the load. We have a type of lossless resistance making up a large part of the internal resistance of the transmitter.

"Ideally", the path between a transmitter and its load is lossless.

Given lossless transmission between transmitter and load, and given a conjugate match, anywhere the lossless system is broken the impedance looking in one direction is the conjugate of the impedance looking in the opposite direction. That`s another natural law.

Reg has argued that high plate, collector, and drain dynamic resistances preclude a matched load. It isn`t the tiny current change produced by a substantial voltage change that counts in these r-f power amplifiers.

What counts in determining the output resistance that these r-f amplifiers present to their loads is the amount of time that the amplifier spends switched off. This explains the high efficiencies of "Class B" and "Class C" amplifiers. Gaps in the conduction affect average conduction as surely as circuit resistance affects average conduction. Conduction gaps and dissipative nresistance to ciurrent flow have the same effect on average current flow. They reduce it, as both impediments to average current are effectively electrical impedance. The difference between electrical dissipative resistance, and electrical current interruptions is that the dissipative loss converts electrical energy to heat and conduction time loss does not produce heat. So we have a loss resistance and a lossless resistance.

The output resistance of an efficient r-f amplifier is efficient beause much of its output resistance consists of lossless resistance. Thus it can use this lossless resistance in making a match to its load without

condemning the amplifier to a maximum of 50% efficiency.

Hi all,

I need help please. I am building a very simple transmitter. I have a 160 uH coilin in the Drain of 2n7000 (N type MOSFET) and a cap inparallel with the coil and the Source to ground. The Gate is pulse with an I/O of the microcontroller. Let's say that I tune the resonance frequenct at 38KHz. This means I have to choose 110 nF cap (F=1/2.0* PI*SQRT(LC)). I tried two different cap I received two different signal base on the material type that I tested. Is it an standard cap material they select for transmitter type of circuitery? If yes which kind is the best, please?

Thanks,
John.

Henrik wrote:
"---just erect the biggest dipole as high as possible....as I really feel we have a statement of general truth here."

Yes, but everything has limitations. When a wave travels 1/2-wave along a wire, that is 180 electrical degrees and marks the point of a phase reversal.

An "elemental dipole" (tiny) radiates energy in proportion to its size and the amplitude of the current. This tiny dipole is so small that current and phase are for practical purposes the same everywhere on the wire. A dipole twice the size of the elementary dipole would radiate about twice the energy because its current also would be everywhere the same on the lengthened dipole because it is still very small in terms of wavelength.

You can make a dipole, each half of which is 1/2-wavelength, and the antenna may have no phase reversals. The summation of all the elements of a 1-wave dipole is not nx the contribution of a single particular antenna element of the big dipole because the current is not uniform. It has a more or less sinusoidal distribution on the wire, being minimum at the ends of the wires and maximum in the middle of the 1/2-wave segments of the antenna.

The changing phase and amplitude of current on a long dipole cause change in the propagation pattern for the antenna as its length in terms of wavelength varies.

I am in search of long telescopic whip antenna elements for a portable loaded HF dipole I am making. The largest I have found thus far are 72" extended, and I need 96-108", about .25" diameter, not more than .50" fattest section, with a threaded or punched base for mounting. I have tried Rat Shack and the usual catalog suppliers (Mouser, Fair Radio, Ocean State, AES) without success. Does anyone know of a mail-order source for such parts?

The current on a very short dipole made from very thin wire isn't uniform -- it's linear. It's maximum at the center and drops nearly linearly to the dipole end, where it's zero. In analyses, end plates are sometimes added, which does bring the current to an essentially uniform distribution.

A dipole twice the size of the elementary dipole would radiate
> about twice the energy because its current also would be everywhere the

If you feed both dipoles with the same current, the field strength, not energy, from the longer one is twice that from the shorter one. So the power (energy per unit time) or power density is four times as great. But the radiation resistance of the longer one is four times the radiation resistance of the shorter one, so the power you're putting into it (I^2 * Rr) is also four times as great. If you feed both antennas with the same power, you'll get the same field strength, power, and power density from both.

The capacitance of coax had always worried me. RG58 is ~ 25 pF/ft so 30 ft. of coax is 750 pF and at 30 MHz that's ~7 ohms - surely significant to a 50 ohm circuit? Even at 2 MHz its only 100 ohms or so.

Still puzzled.

I may be doing the guy an injustice but check out his qrz.com picture. That's a big mast/antenna plus a lot of gear. None of that was free. Still, times are very hard in the former Soviet Union, so maybe he does need help. He's certainly a lot less well off than most hams in the west. I'd say send him the money if it doesn't hurt you, but don't feel guilty if you don't. I don't think he'll spend it on booze or drugs like most panhandlers would but maybe on a new rig. ;-)

Roy,

When reading your post 'between the lines', I believe the theoretical antennas you are talking about were meant to radiate broadside to the wire.

There is another type of antenna that does not have that constraint, that I find of interest. If you have several hundred feet to play with it is relatively easy to put one up, but it is not rotatable and can have a relatively sharp pattern at higher frequencies.

What I am thinking about is called a type of 'traveling wave antenna'. It is similar to a beverage but operates more on the principles of a long wire. In fact, I have also seen it called a 'terminated long wire'. This consists of literaly a long wire fed at one end, and the other end connected to ground through a resistive load of a few hundred ohms. The height of the wire above ground, unlike a Beverage, is 20 or 30 feet in the design I have seen.

There will be a constant uniform current distribution along the wire across a broad range of frequencies. According to Kraus the radiation pattern is conical shape, with the angle of the cone from broadside increasing as the wire gets longer. The limit seems to be about 60 to 70 degrees from broad side for a very long wire. Of course gain increases as the wire gets longer. When I say 'gets longer', I mean in terms of wavelength, so you can either physically make the wire longer or increase your frequency.

When I get a chance I will model it in Elnec demo and see what it can do.

Roy Lewallen, W7EL wrote:
"The current on a very short dipole made from thin wire isn`t
uniform--it`s linear."

Yes. I mis-spoke. Obviously, when the wire ends, there is a
discontinuity in current.

Roy also wrote:
" feed both dipoles with the same current, the field strength, not
energy, from the larger one is twice that from the shorter one."

Yes. I mis-spoke again. When you double the volts per meter, the power
is quadrupled.

Sorry I was so careless. The point I was so poorly trying to make was
that radiation from a too-long antenna can produce destructive
interference in a desired direction, so longer is not always better.

Best regards, Richard Harrison, KB5WZI

You'll have to judge if its sincere. My bet is yes.

Several years ago I commonly sent $5-10 with certain QSL's(and science colleagues) to Russia--not that I needed the QSL. This was unsolicited: some of these guys hadn't seen income in many,many months. The bad news is that the mail was commonly opened long before it got to the OM's it was sent to. It was frustrating in the extreme for both parties.

Hi Matt

I don't know whether the guy is legit or not, however, I have received many such letters over the years, especially when I was working all African continent, which I finally achieved.

I look at it this way. There's no way I could afford some of the elaborate setups some of the stations I have spoken with boast about on the air and on their QSL cards.

I know we all have our ups and downs and perhaps when they assembled their stations they were doing great financially and have hit a recent downturn. So I do not try to judge the persons motives for asking for money.

But it seems to me that if I'm running an Hw-101 into a dipole and their running 2 gigawatt boosted newer Kenwoods into massive beams up a couple of hundred feet. Hey eBay is everywhere. They can sell something if their so poor they need to beg for money.

Look at it more realistically, would you give someone rolling a Benz a free handout when your still holding your Nash together with bailing wire and bubble gum?

Roy,
What you are quoting I.E historic attempts to gat constant current is
well
known. The CCD also attempted to do the same thing.
I also agree that such actions are not the best way to go. What I did
is to look at things from a efficiengy/length point of view as
follows.
Looking at the current curve of a half wave dipole it is obvious that
the highest current is at the center and zero at it ends. In looking

for maximum efficiency/per unit length I chopped off the ends where length produced minimal gain. Methods of doing that are well known, one only has to decide what area
under the current curve they are willing give up in the pursuit of efficiency.
If one then superimposed TWO modified, chopped short current curves on a half wave length it takes on the shape of a 'quasi' collinear with a center space
showing empty space or minimal radiation. To be able to make this truly
collinear one has to put a phase mechanism at the center so the repeating current curves are on the same plane.This I did thus leaving two high efficiency shortened curves at each end where the maximum current peaks are at a distance from each other to produce a collinear array.
The question in the past has been does it produce more gain ?
Worth while gain was stated to be 1 db or more and my main detractor rediculed the idea that such an antenna could produce gains.
As no one on this group disagreed with that position (inluding the doctor)
I then became a target in a similr fashion as the fractal,e/h antenna or a particular commercial antenna manufacturer and unfortunatly it brought out the worst of me in retaliation. Never the less, my design does what I say it does,
I have shared it with all and over the years have placed a page tho poorly done,
on the web. I am holding nothing back,done modeling that show db gain where
detractors would only accept dbi modeeling. I might add that with many good and experienced modellers in the group it would be a futile attempt to counter
suggestion that I made programming errors as I was not using EZNEC programs
leaving me a tough row to how. All of the above is basically what I gave on the last go around on the thread remarking on collinear gains e.t.c a couple months ago as you well know.
I ofcourse still hold you in high regard but would also point out that one poster pointed out another old book that did not point to the notion in
disfavour.

Regards
Art Unwin KB9MZ......XG.
was stated as one db or more

Andy Cowley wrote:
"The capacitance of coax has always worried me. RG58 is ~ 25 pF / ft so 30 ft of coax is 750 pF and at 30 MHz that`s ~ 7 ohms - surely significant to a 50 ohm circuit. Even at 2 MHz it is only 100 ohms or so."

The coax does not appear to either the aerial or the receiver as a shunt capacitor in most instances. An infinite lossless coax would present a pure resistance.

A lossless coax does not discriminate against higher frequencies because all the energy entering one end emerges the other end regardless of frequency.

Capacitance produced by a transmission line is usually caused by reflection. A peculiarity of an 1/8-wave open circuit stub is its capacitive reactance which equals the surge impedance of the line.

At low frequencies, pieces of coax can be conveniently cut to length to produce a desired capacitance so long as the length is very short in terms of wavelength. If the length of the capacitor so constructed becomes too long, reflection of the traveling wave produces a phase displacement and an impedance variation often associated with SWR.

Reflections are avoided in coax by terminating it in its characteristic impedance, a resistance.

Best regards, Richard Harrison, KB5WZI

Many moons ago, the first CB hand helds sold after legalisation of CB in the UK (1981) jad a 102" telescopic. Radio Shack (Tandy) sold these under the "Realistic" brand name. MAybe although when requested for a whip they have not got one, but try asking for a replacement antenna for Realistic TRC xxxx (cannot remember the number) you will get a different answer. Maybe also try the CB spares suppliers. These sets were sold here under at least a dozen different brand names, Alba, Harvard, Maxcom. Incidentally, I used to have a similar set from the USA, a Hy-Gain 40ch multimode. I've never yet seen another non-military SSB handy.

I'll tell you what, it didn't half look strange - someone talking into a handy bigger than a house brick with a 9 foot whip on it!

Good luck

Andy,

Assuming the Halos are 50 ohm antennas, you just need two lengths of 75 ohm coax to phase them. Each piece of 75 ohm coax is 3/4 wavelengths long, which, at 144.5 MHz, would be about 61 inches long for RG59 foam, or about 54 inches for garden variety RG11. First make sure the two halos are identically adjusted; now run the 75 ohm coax from each halo to a UHF T connector. Connect 50 ohm coax from your radio to the third leg of the T connector. You will want to space the halos as far apart as possible. Using the full length of the RG59 is not unreasonable. I used this method to stack a pair of Cushcraft 7 element 2 meter beams, and they worked fine. SWR at the end of about 50 feet of coax was around 1.2:1. I used it for both SSB and repeaters at the high end of the band. After 10 years there was no problem with corrosion of connectors or such.. There may be some advantage to using a nonmetallic mast, like plastic water pipe (the more rigid white kind).

A couple years back, I did a fairly extensive side-by-side comparisons between a Moxon rectangle and an equally sited monoband Hex Beam--both home brew antennas on 10 meters. I found no discernable difference in performance between the two (my short-boom 3-element Yagi did a couple dB better than either of them). Considering my hex weighed less than a pound and was virtually invisible, I thought it was pretty impressive. No magic, though!

John,

Do not use ceramic capacitors that are meant for bypassing. Mica is best,
but any of the film capacitors like Polyester or Polyproylene should work.
If you have old paper or mylar capacitors, they will be OK. I have seen
ceramic capacitors not work in a 50 KHz tuned circuit.

I hope I am wrong, but this sounds like a panhandler on the street
corner asking for a little change for some food while a cigarette
hangs from his mouth.

Too many tragedies for me. He can't walk *and* his house burned down.
But, send the money and he'll send a second color picture of his new
antenna.

I don't mind fostering internation good will, hell, I had a Russian
ham ask me for a picture of the Grand Canyon. So the XYL and I used
that as an excuse to drive up there and take a photo of me in front of
the canyon and I sent it to him along with a copy of Arizona Highways
magazine. (Okay... we were going anyway:)

But when I advertised a transceiver for sale and a Russian wanted to
buy it and wanted my bank account number so he could direct-deposit
the funds, I rang up "NO SALE." There have to be limits on goodwill.

My $.02

Dear Richard,

Yep, I know about coax as a transmission line. The subject here was a
random wire connected to a receiver via a length of coax. I.e. the wire
connected to the centre conductor and nothing connected to the shield
at the aerial end. Shield grounded at the RX end.

```
RX + ------------------------------------------------------------------
-------------------------
|
RX GND COAX RANDOM WIRE
```

I think my figures apply here, don't they? Doesn't the coax look like
a capacitor shunting the RX input?

If you have the segment capacity, you might want to include models of all major nearby conductors in your antenna model - in addition to the house wiring you mentioned, you probably have power lines, metal yard buildings, metal fences and other antennas close enough to distort the patterns at very low levels. Perhaps even the tower that supports it.

Reflection or scattering from these things will probably make a difference at those levels. And their effect will vary as you rotate the beam.

"BUILD", included in the freeware 4NEC2 package, can generate approximate models of metal buildings, roofs, etc, which you could then import as a NEC file into your NWP model.

no, you can not just consider it a capacitance in the general case. for every infinitesimally small piece of shunt capacitance there is also a piece of series inductance. This is what gives coax its characteristic impedance and velocity factors. for a very short piece (much shorter than a wavelength) you may be able to make a reasonable approximation with a capacitance as the series inductance will be small, but as others have shown even at 1/8th of a wavelength there is considerable effect from the length.

Hi,

Having worked with Peace Corps when I was fresh out of college, I can understand the difficulties that many people around the world can experience.

Anyone can print a bunch of qsl cards, even expensive ones, and mail them out. Same thing on the forums, is it my huge antenna farm or a photo of some other station ? We do not know.

That station you and others worked could be just a small station or it could be a large one and funded by some dishonest people.

We may never know.

However, as the old saying goes, a fool and his money are soon parted.

If it was me, I would keep my money.

Hi Andy,

Puzzlement comes from the lack of an answer, and certainly from
knee-jerk responses.

Your capacitances are figured as they should be, and everyone is
either too focused on them, or in denial through other discussion.

What is missing, however, is that you (and especially the others) have
neglected to observe that those incremental, equivalent capacitances
are only available through corresponding incremental, equivalent
inductances. You need to observe them in like manner to what is
quoted above. You then need to combine them into the mesh they
approximate (standard Network Analysis, often discussed within the
first 50 pages of any text).

Even with the appearance of increasing shorting reactance as the cable
gets longer, this is offset by the increasing opening reactance as the
cable gets longer. The combination of the two guarantees that the
cable does not present a short to a source due to this capacitance,
and does not present an open to a source due to this inductance. For

cable, with the initial application of energy, this presents a characteristic Impedance that is entirely resistive (the combination of the two reactance vectors balance and the apparent resistance that comes with losing a signal to a distant load - or in this case, an infinite sink). In the real world, this value is 50 Ohms. This value is immutable through frequency and source/load conditions typically encountered. That is, the capacitance does not reveal itself independently (to offer the prospects of shorting the source) due to standing waves, mismatch (yes, I know its the same thing), or (gasp!) common mode currents, or imbalance (yes, I know its the same thing).

This balance game and initial conditions is found from 1MHz through 10GHz (with only the loss properties of ohmic resistance and dielectric dissipation modifying the results). Beyond these fringes, cable becomes sensitive to other physical features that were ignored as marginal.

Rick and Larry
Thanks for the feedback. I have read CEBIK on Moxon rectangles and note quite a bit of advantages. The light weight of the multiband HEX BEAM however seems to be offset by the HEAVY PRICE TAG. So tit for tat it appears that performances are about eaqual but which one fits best in your environment may be more the issue

Wes, you are correct that some radiation occurs in the 'wrong"
direction.
The idea so that gain/efficiency per unit length as high as possible
(the header of this thread by the way and not the Unwin antenna)
is if there is radiation in the Wrong 'direction' it behoves one to
shield
it or to phase it so that it does radiate in the correct direction..
This aproach is very important if one is to achieve a high order of
merit per unit length, an aproach that has not yet gained acceptance
or deemed usefull.
I also agree that rotation is a very important part of 'merit' and
cannot be omitted in any aproach with respect to gain/efficiency per
unit length.
Warm and fuzzy ! How can you say that when I have so many bricks
thrown at me?
Regards
Art

1730. Re: Gain and efficiency

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-01 18:40:13 UTC
From: Roy Lewallen <w7el@eznec.com>

Source record: 132069

The Beverage antenna, though quite directional, has low gain because of the loss involved. It's also typically considerably longer than a wavelength. I don't know how the antenna you describe compares, but I suspect it would also be lossy.

My discussion was limited to antennas in space which are one wavelength long (or ground mounted verticals that are a half wavelength). Straight wires of this length inherently radiate broadside to the wire. I didn't consider the case of bent wires of this length, although that would add an interesting dimension to the study. Certainly, there are many configurations you can make with longer wires, with a wide variety of patterns, but they're not relevant to the case at hand.

Don't use ELNEC or any other MININEC-based program to model the antenna if it's lower than about 0.2 wavelength -- actually, recent work indicates that this limit might need to be raised if horizontal wires are much longer than a half wavelength. You'll get results that can be very wrong. Instead, use an NEC-2 based program. Unlike MININEC-based programs, these can accurately model antennas having low horizontal wires.

As Roy said, its time to cut some aluminum (well actually, its already done). The beam is going to be mounted on a roof top tower (10' high) without guy wires. The house wiring will be just over 1/4 wavelength away (below). Think I better take all those aluminum pieces for antenna's and coax spools out of the attic too...

Scott.

Larry, the manufacturer of the Hex beam was heavily hit by this group.
I would say it was as heavy as that delivered on the subject of
E/H antennas tho it did give some respite for Fractals.This is many
years ago
and the owner does not now frequent this group. At the same time I was
discussing my design and ofcourse got many bricks thrown at me so I
now limit the subject to once per year. I thought the hex beam was
good and the owner did not get the credit he deserved. That is the
nature of this group to 'new'
or 'differnt' ideas so you have to accept the good with the bad.

It's probably more legit than much of the email we all receive.

Back in the mid-1950's I got a letter with a QSL from VR6AC on
Pitcairn Island asking if I could send him some radio parts.
Considering the lack of electronic parts stores in the area, I thought
that was not an unreasonable request. I didn't have any inventory of
parts so I passed it on to the local "candy store", but don't know if
they responded.

Andy Cowley wrote:
"Doesn`t the coax look like a capacitor shunting the RX input?"

Depends on coax length in terms of wavelength. The center conductor and inner surface of the outer shield are tightly coupled. There is a discontinuity at the unconnected end of the coax. That is, only the inner conductor connects to the aerial. There will be displacement current between the aerial and the outer surface of the coax shield. There will also be conduction looping around the shield`s inner and outer surfaces.

The discontinuity at one end of the coax will cause reflections. Is the coax so short that phase shift along its length is not significant? If the coax is not so short, Andy may be better off with open-wire as Zepp users are fond of, or a low capacitance shelded cable most often used wih autmobile medium wave receivers.

Best regards, Richard Harrison, KB5WZI

1737. Re: Hex Beam?

Newsgroup: rec.radio.amateur.antenna

Source record: 132075

I encourage anyone who feels that the Hex Beam (or any other antenna) was treated unfairly by people on this newsgroup to go to groups.google.com and do a search on "hex beam" for this newsgroup. What you'll find is generally positive comments about the beam's small turning circle and respectable performance for its compact size and weight.

You'll also find people commenting that they don't believe the claim that the manufacturer was making that the Hex Beam exhibits gain of 10 dB relative to a dipole. This has nothing to do with whether the Hex Beam represents a "new" or "different" idea -- it's simply that the manufacturer has failed to convincingly demonstrate, either through measurements at a certified test range or by modeling, that his antenna's performance greatly exceeds what's possible for such an antenna as predicted by theory which has been shown to be good for the past couple of hundred years. I hope that the people on this newsgroup continue to be skeptical about claims for performance that defy all known physical laws -- I for one certainly will be. Perhaps the purveyors of such claims will find more fawning acceptance at alt.magic.

> power levels where heating might be a problem.

==========

I am entirely unfamiliar with Fair-Rite and their 70 series materials. But
I don't consider that to be any disadvantage.

But the answer to your question is obvious! When over-heating is a problem
at HF the losses must be too high.

==========

> The two switching
> supplies I've designed for production have used ferrites which would be
> very suitable for HF wideband transformers.

==========

But have you ever designed equipment or specified their use, for example, at
HF at high power? Whatever you mean by high power!

==========

What ferrite characteristics
> are you thinking of that would make some unsuitable?

==========

It is "Hysteresis Loss", watts per cycle, which increases directly with
frequency. These days ferrite manufacturers seem to state performance
characteristics in wierd units which nobody understands and which circuit
designers simply ignore.

There's a great deal of difference between 30 KHz and 30 MHz.

Regarding use of ferrites there is no 'design procedure' left in the job. So
called designers, just like everybody else, just use the particular pretty
coloured ferrite rings which other so called designers have found 'work' in
similar applications. And if it 'works' then that particular colour finds
its way into the mass-production process. If a colour doesn't work then the
circuit designer tries another colour or 'mix' which DOES work at the

frequencies of interest.

Circuit designers can find all the mixes and colours and dimensions for particular applications in such reference sources as ARRL and RSGB constructio handbooks. Manufacturer's data is redundent. It has served its purpose. It is necessary only that manufacturers don't change the 'mix'.

I must make it plain I have no complaint whatsoever about this sort of design procedure. It would make no difference if I did. It is obviously the most economical way of designing equipment which incorporates ferrites. The universe is ruled by Economics.

==========

But to ensure the above-described very sensible practice does not lead one astray when projecting knowledge into less certain regions it should be said that ferrite core loss is only half the picture. If there's no significant flux in the core then there's no significant loss in it.

One type of HF transformer is a misnomer. The core loss due to hysteresis is largely irrelevant and use of materials having low loss only at VLF is acceptable.

For example, take the common-or-garden 4-to-1 impedance-ratio BALUN. It does indeed behave as a transformer of sorts up to a certain cut-off frequency. There is sensibly no core loss because, over the very wide operating frequency range, there is sensibly no flux in the core. The winding consists of a relatively few turns of small-diameter coaxial cable. Or it may consist of a winding of something like twin speaker wire (which I have occasionally recommended because it has even lower loss.).

This short length of transmission line carries the whole of the Tx power to the antenna. The two wires carry equal and opposite currents. The resulting flux in the core is negligible. Result - neglible core loss!

Construction of such 'transformers' has been described in a small book by an American amateur whos name I forget. But he does not explain very well how they work. So far as us amateurs are concerned this doesn't matter. Essentially the loss occurs only in wire resistance - the same loss which occurs in the very short length of line used for the winding.

At the low frequency end of the frequency range the mode of operation changes. It behaves as an inefficient choke. The pair of line currents become unequal, the core flux and hysterisis loss increase. But who cares if that occurs below 1.8 MHz.

By increasing the number of turns the ampere-turns and core flux in the choke decrease because the choke impedance is proportional to the square of the nunber of turns but the voltage available across the choke to drive current through it tends to remain constant. The available voltage depends only on the power output from the transmitter when correctly loaded. So the LF response improves with the number of turns.

The high frequency response of a 4-to-1 balun fails completely when the length of line on the 'transformer' is 1/4-wavelength or more. Keep it to 1/10th-wavelength, preferably less. Even then the transformation ratio suffers at the VHF end. This not a matter of great consequence - it need be only the right ball park.

For numerically interested readers, to analyse insertion-loss performance of a 4-to-1 balun download program BALUN4 from website below. The extrordinary low loss at HF using VLF ferrites is accurately estimated. Compare with the measured values obtained by the book author whose name and call-sign unfortunately I cannot remember.

Baluns could not have been invented until ferrites had first been inverted (I think) in Holland during the starvation which occurred there during WW2. Our friends the Japanese physicists were also in there somewhere. Please correct if needed.

To irritate Roy, and that other person who knows nothing except about Italian clowns, the program is not zipped up, can be downloaded in a few seconds, free to USA citizens and can be run immediately without a 3-week college training course. The only numerical value needed from ferrite manufacturers' data sheets is material permeabilty - if they feel happy to disclose it. ;o)

Well, we've come a long way from "Low budget impedance transformers". I hope you have enjoyed the entertainment. There's more ways than way one of getting kicks out of Amateur Radio. Long may the pastime survive!

I've just come to the end of a bottle of Californian Ruby Cabernet. The shops are shut. Good for the arteries I'm told. I still love Yanks. My 4-by 1.5 volt keyer battery has now gone flat.

Hic !

Don't forget BALUN4

Hi All,

The LAST time around, it was less than 1dB (which was the same amount
available to Cecil's simpler dipole and simpler method of tuning).
Art did not dispute this figure, and instead offered to beg inability,
incapacity, or some other excuse (too emotionally drained perhaps) why
he couldn't do this simple chore.

Seems that when Art recovers (from whatever) we begin again as if the
last discussion never took place (and no lesson learned) and we run
through the obvious problems once again to find Art flagging from
inability, incapacity, or some other excuse (too emotionally drained
perhaps) why he couldn't do this simple chore.

As a variation upon this theme, Art sometimes suggests it is our
fault that the numbers do not do better. He has none to offer, and
certainly no better method is suggested, "just take my word for it."

It is more than apparent that if Art were simply to start at the last
point left, and answer the question quoted above ("the world
wonders"); that this would all be over as an exercise in noting the
obvious. For both Art and the eh/cfa/fractal crowd, an answer is an
end - better to keep everyone guessing - or demanding they prove him
wrong which again requires that same question answered... see a
pattern?

> I don't consider that to be any disadvantage.

I'm sure you don't, since you could easily become informed if you were interested. Their data are on the web and easy to find. I tend to use Fair-Rite as an example, because Amidon has long been a major supplier to amateurs, and they have sold Fair-Rite ferrites and use their ferrite designations.

> But the answer to your question is obvious! When over-heating is a problem
> at HF the losses must be too high.

I agree entirely. But don't confuse cause and effect. The losses are too high by definition if the transformer is overheating. It's the overheating that's the problem, not the loss.

But overheating isn't a problem unless considerable power is involved. That's hardly a reason to proscribe the use of low frequency ferrites for wideband transformers for all applications. You'll find these materials to be used almost exclusively for HF broadband applications in a wide range of products, from transmitters and receivers to spectrum analyzers and other test equipment.

The fact that a transformer can get hot at a high power level doesn't necessarily mean that the loss is otherwise unacceptable. For example, if you have a transformer with 0.5 dB loss -- acceptable for nearly any application -- and run a kW through it, it'll dissipate 100 watts. That'll cause overheating unless the transformer is physically pretty big. At 1 kW, the loss is too high because the transformer gets too hot. At 10 watts, the loss is perfectly acceptable.

Advising people never to use low frequency ferrites for HF wideband transformers because they can overheat when high power is applied is like advising them never to use cores smaller than a foot in diameter, or resistors with anything less than 100 watt dissipation rating. The professionals use these materials for this application -- there's no reason for amateurs not to.

Really, I mean enough that overheating becomes a problem. I routinely
use a ferrite core with a little over one inch OD for a balun, and run
up to 300 watts through it. So for that size core, I'd call "high power"
something over 300 watts. There are a lot of applications that don't
involve this much power.

Chuckle. You obviously hang out with a different bunch of design
engineers than I do.

You might take a few moments and drop by the Fair-Rite web site or the
competing site of your choice. You'll find that the resistance of a
winding on a low frequency core doesn't increase linearly with frequency
as you say, at least over the HF-VHF range. It tends to remain fairly
constant with frequency. (I trust that your program reflects this.)

> There's a great deal of difference between 30 KHz and 30 MHz.

Yes, indeed. For a given applied voltage, the flux density is inversely
proportional to frequency. So a core that can easily saturate at 30 kHz
will be nowhere near saturation at 30 MHz, given the same voltage across
a winding. It's the "hysteresis loss" that gives rise to the resistive
nature of the impedance at HF. There's nothing wrong with it.

You won't be able to get a low frequency ferrite core anywhere near
saturation at HF -- it'll go up in flames at a flux level far below
saturation.

Somehow, I get the impression that the hydrogen assisted the burning process. Helium, being inert, would have helped keep the oxygen away from the blaze. Too bad Hitler wasn't on that dirigible.

My present method with an ordinary house is to mount a 1/4" plexiglas plane in the shack window. The knife switches are mounted on the inside and the 450 ohm ladder-line vertical loops are mounted on the outside about six inches apart. It works extremely well here in Texas where the temperature rarely gets below freezing. The switches are in the plane of the screen so I can pull the window down if it gets extremely hot or cold.

Unfortunately, the conjugate matching theorem only applies to linear systems and we cannot achieve more than 50% efficiency without non-linear amplifier sections, e.g. AB amplifiers. Each section in a push-pull AB amplifier is non-linear over part of the range. Can two non-linear amplifier sections be combined to obtain a linear amplifier? Is 99% linear combined with 1% non-linear, linear or non-linear? :-) Isn't that like adding two irrational numbers and obtaining a rational number? :-) I have long suspected that the lossless resistance seen looking back into an amplifier is the load line. If so, virtually all low impedance sources are near a conjugate match.

> If yes which kind is the best, please?

John, in my humble opinion, you just cannot go wrong with a Texas Aggie cap.

Seriously, ceramic caps, for instance, are intended for bypass use where the
DC component never allows the dielectric to be exposed to a reverse voltage.
I tried to use disc ceramic caps in my antenna tuner. They literally burned up.
Someone told me that the ceramic dielectric actually physically moves when exposed
to pure RF.

For RF capacitors with no DC involved, mica, silver mica, air variable, doorknob,
vacuum variable, etc. are to be used. Electrolytics and ceramics tend to malfunction
unless they are biased with DC.

If he has a modest fixed income, the more expensive QSL cards would make it
more legit, wouldn't it?

Source record: 132090

I've heard the lip-flap about the hex beating up on much larger Yagis. However, big beams with sharper patterns can exhibit fairly deep nulls at some elevation angles--while "low-gainers" tend to have broader and smoother patterns. This dynamic might easily fool the unwary and cause 'em to think there's magic afoot.

Hi,

Can anyone help me identify brand/model of this antenna I came across? I was told it was a HyGain vertical, 10-40 m, however it doesn't look much like the 10-40m HyGains on the website. 3 coils, and it does seem to tune at around 10/15/20/40 m

If anyone could point me to a manual that's got tuning measurements, even better...

Photos of the thing are at

He didn't say his hex beam was good, Art. Nobody would have
disagreed with that. He said, in so many words, that his hex
beam was better than sex. :-) The hex beam is cute and performs
well but it is no better than other similar beams (and certainly
does not possess supernatural powers). I seriously doubt that
anyone can tell the difference during normal operation between
a hex beam and the decades old X-Beam.

Gain means that some photons are allowed to materialize in a certain region
at the expense of not being allowed to materialize in another region. Aren't
you glad you asked? :-)

> Gary
> K4GPB

I put a hole right through the roof. Installed phony 3" PVC
"vent pipe" with two 90 degree curved elbows, so the opening in
the PVC faces down. The coax goes up into the first elbow,
horizontal through the short connecting pipe, then down through
the roof into to the attic. I cram insulation into the first
elbow from the outside.

I have an OLD HyGain vertical which looks almost identical, except that it has an additional coil and covers 10/15/20/40/80. Works good, but afraid I don't have a manual or a model number.

From: artie <silli_artie@hotmail.com>
Message-ID: <011120021546028553%silli_artie@hotmail.com>
Source record: 132102

Here's how I teach antenna gain (from a demonstration I saw many many years ago -- I wish I remembered who did it so I could thank them).

Think of the RF you're feeding your antenna as a nerf ball (spongy foam thing).

Holding it in the palm of your hand, it's radiating out equally in all directions -- the perfect isotropic radiator.

Now hold it between two fingers, thumb and middle finger at north and south poles, and squeeze them together.

You've got a dipole radiation pattern now. Notice that the ball bulges out farther in some places, and less in some places in comparison to the original (unsquashed) ball. The places it bulges out larger, acting like a larger ball, those are the places where it has "gain" over an isotropic source.

But you've still got the same ball -- the same amount of energy going into the antenna -- so all you're doing is squashing it so more of the ball (more energy) goes in one direction, and less goes in others.

Highly directional antennas (yagis, dishes) can focus most of the energy in one direction, but the antenna can't *make* energy.

HTH...

If you're interested in *that* explanation, pick up a copy of Pozar's "Microwave Engineering" -- the inside front cover lists as "useful results" Maxwell's equiations in vector form... The book starts from there...

Seriously though, the nerf ball thing (or using a partially inflated balloon) lets you get across a bunch of concepts (radiation patterns, isotropic radiatiors, the need for a reference in gain calculations) in a very simple and visual manner (and without making reference to Mr. Maxwell, or vibrations in the lumeniferous aether).

Is there a product made for supporting coax as it runs across (and in contact with) the length of a roof? I'd like to hold it up a bit so that it doesn't rub against the roof shingles and wear them out. (I've worn them out under the coax once already, and I'm not going to repeat that mistake.) I can suspend it - but I'd much rather support it.

Thanks for any help!

>n excuse to drive up there and take a photo of me in front of
>the canyon and I sent it to him along with a copy of Arizona Highways
>magazine. (Okay... we were going anyway:)

Hmmm...

I could sure use a saturated f/22 (velvia: now and forever!) slide of Red Rock Canyon, with the moon peaking over Cathedral Rock, as it glows with sunset alpenglow over the silky smooth stream. Polarized blue sky with a hint of cloud wisp preferred. Graduated 2 stop neutral density filter recommended. Three second exposure. Try 100mm. 81A or 81B also. Use a tripod. Fill flash down 3 stops for hint of 5000 degree blush.

A horse crossing the stream would give a nice visual balance...

Last time I tried this pix, all of Arizona from Phoenix to Page was closed from fire danger...

FYI for those not in the know...Arizona Highways is not a travel guide. It is the best landscape periodical in the world.

Nope. Where do you think the fire started?

> Looking at the film record it is CLEAR that the flame front came from
> within.

That was after the fire was started.

> The file CLEARLY shows an explosion in the tail of the bird.

Not in my memory. There was a whoosh of burning hydrogen up and
outward, but that was no more an explosion than any gas jet.

> The envelope was the LAST to burn.

The first to start, last to finish.

Not likely. It burns and moves up and away so fast it didn't do
much. That is why after big whoosh of hydrogen burning the envelope
was still burning.

> process. Helium, being inert, would have helped keep the oxygen away
> from the blaze.

Perhaps. But helium also rises away. Unless you could have
contained it between the blaze and the atmosphere, I think its
rising would have drawn oxygen in as much as helped keep it away.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <us66r162u0etff@corp.supernews.com>
Source record: 132110

There are a number of varieties of ceramic used for capacitors, each with its own characteristics.

Z5U, Y5V, and similar ceramic capacitor types have ceramic with a very high dielectric constant. This makes them physically small, so they're great for bypassing (where the low inductance and high self resonant frequency is an advantage) and fine for coupling capacitors (where poor temperature stability isn't a problem). Z5U types can be microphonic, piezoelectric, and hygroscopic, have a terrible temperature coefficient, and exhibit nonlinear properties such as "hook" and "soak" so they're suitable only for applications where these characteristics can be tolerated. There are, however, a very large number of such applications. I've used physically small Z5U units as blocking capacitors with up to several hundred watts of RF with no problems. This is probably the most common type of ceramic capacitor you'll find in your junk box.

X7R and similar "stable" types are good when moderate to good temperature stability is required. They're larger than Z5U for the same capacitance. These types are good for most other applcations except those requiring extremely a very low temperature coefficient, for example moderate-Q tuned circuits or filters used in a moderately temperature controlled environment.

NPO or C0G types have a very low temperature coefficient, better than any other common capacitor type including mica and styrene. They can be used for high-Q tuned circuits and precision filters, and are in my opinion the best choice for oscillator tank circuits.

Ceramic capacitors come in several varieties, most commonly disk, monolithic, and radial leaded tubular ("dog bone"). Monolithic parts have low inductance and generally very good RF characteristics. Tubular parts also work very well at RF. I don't have as much experience with disk units, but do know that the capacitance can be a function of frequency because of the distance the current has to travel along the surface before it encounters most of the capacitance. Their RF properties are generally substantially inferior to monolithic types, which contain a sandwich of alternating metal and ceramic layers, with alternate metal layers connected in parallel along the ends of the ceramic block. This produces very low parasitic RF impedance and inductance.

Electrolytic capacitors require a DC bias to maintain the oxide coating which furnishes the insulation -- it's grown with an electrolytic process and will slowly dissolve with time if DC isn't present. (Its thickness will also decrease to just support whatever DC voltage is applied, so don't abruptly raise the voltage on an electrolytic capacitor that's been at one voltage for a very long time.) But ceramic

capacitors have no such requirement. High quality commercial products abound that use ceramic capacitors for the applications I mentioned, with and without DC bias. And they're not polarized, so there's no such thing as a "reverse voltage" to a ceramic capacitor.

An antenna tuner is a very demanding application for any capacitor. Huge voltages and/or currents can be involved, and only capacitors specially designed to handle these extremes (such as transmitting micas) are likely to survive. A few amps through a moderate sized monolithic ceramic capacitor shouldn't be a problem, but a tuner application might result in a lot more than that.

> Looking at the film record it is CLEAR that the flame front came from
> within.

Well, in 1998 that was refuted by some professors at UCLA:

William Van Vorst of the University of California at Los Angles and
Addison Bain, an independent consultant, have gathered evidence that
hydrogen could not have caused the explosion. Film footage and
witnesses of the crash describe bright yellow flames burning
downwards, but hydrogen would only burn in an upward direction with
a colourless flame. Several helium-filled airships also crashed and
appeared to burn in a similar way. A second piece of evidence comes
from chemical analysis of fabric used to cover the airframe. Van
Vorst and Bain discovered the that sealant used on the cotton - a
mixture of iron oxide, cellulose acetate and aluminium powder - was
extremely flammable. "The total mixture might well serve as a
respectable rocket propellant, " says Van Vorst. Finally, the design
used to attach the cotton to the airframe did not have any mechanism
for preventing the build up of electrostatic charge. They believe
that when the skin finally discharged, it passed a current through
the skin direct to the frame, igniting the sealant on the fabric.

After the crash Hugo Eckner, chairman of Zeppelin company, publicly
blamed the US for the accident by cutting off his supplies of
helium, forcing him to use hydrogen. However, Van Vorst and Bain
point out that the Graf Zeppelin , which was being constructed at
the time of the disaster, suddenly underwent a series of
modifications to reduce the risk posed by the fabric. These included
doping the fabric with a fireproofing agent and using copper rather
than aluminium in the sealant to prevent the build up of static
electricity. The researchers also discovered a letter from Otto
Beyersdorff - an independent investigator hired by the Zeppelin
Company - who blamed the fabric for causing the blaze. "Clearly,
there must have been strong suspicion that the fabric was the real
culprit, " says Van Vorst.

(not that that press release is entirely correct, but it is at least
in the correct direction)

The same information appeared in senate testimony and in popular
science in 1998. Long article:
http://www.fas.org/spp/civil/congress/1998/s981006-zep.htm

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <us674hh8t86ma5@corp.supernews.com>
Source record: 132113

Gain is simply a ratio. When transmitting, the gain of the antenna is how strong a field will be produced compared to some reference antenna to which the same amount of power is applied. When receiving, it's the amount of power delivered to the receiver compared to a reference antenna immersed in the same field. The gain of an antenna is the same when transmitting and receiving. The gain of an antenna is generally different in each direction, both azimuth and elevation, and it's strongly influenced by the ground and other environmental factors. A graph of gain vs direction is called the antenna's pattern.

A single number for gain doesn't mean anything unless you know what the reference antenna is, and in what direction the gain is being stated for.

Yep, the balloon illustration is one I use to explain destructive interference and constructive interference. Some people seem to think that destructive interference of energy can occur without a corresponding constructive interference involving that same energy. If energy is actually destroyed within a transmission line, where is the resulting matter created? If energy is created within a transmission line, where does the required matter to energy conversion come from?

Does 75 joules plus 8.33 joules really equal 133.33 joules?

Speaking of the lumeniferous aether, it seems that measurements around black holes have proved that such really exists as opposed to absolute nothing. There seems to be a definite difference between a vacuum within our universe and the nothingness outside of our universe. Of course, the nothingness outside of our universe is hard to measure. ;-)

1778. Re: Gain

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-02 00:48:34 UTC
From: fractenna@aol.com
Message-ID: <20021101194834.01210.00002014@mb-mk.aol.com>
Source record: 132117

Gain is a mathematically defined quantity which is unitless:

G=4pi Ae/(Lambda^2)

where G is gain--a number which is NOT in dB; Ae is the effective aperture of the antenna, and Lambda is wavelength.

For a large circular aperture, such as a dish,

Ae=pi(D^2)/4

so to good approximaton

G=10(Dlamb)^2

where Dlamb is diameter in wavelengths.

Gain is the factor by which an antenna manifests, in a particular direction, more radiated power compared to an antenna radiating equally in all directions, that is one with a spherical or 'isotropic' pattern.

It is not possible, instantaneously, to get an antenna to have gain isotropically. Conservation of energy, and all that.

Typically gain is given in dB so to good approximation

G(dB)=10log(10(Dlamb^2))

Hope this helps.

Lets try another analogy. Put a lit candle on stand in the middle of the room. The room will be evenly illuminated. Now put a big mirror behind it; part of the room got brighter and part got darker. You just picked up 3db of gain (or therabouts). Nothing got amplified, there is still the one candle. Now if you are real smart, you can put a lens in front of the candle, and get a bright spot on the wall. You just got a lot of gain, but only in one direction. Same with antennas, the more gain, the more accurate you have to be in pointing it.

Howdy,

Getting gain from an antenna is like getting increased light from the flashlight bulb in your flashlight.

The reflector "aims" the light in a particular direction. The power of the bulb is the same but. oh my, what a difference in illumination.

An antenna achives gain in the same way. Instead of radiating in all directions like a light bulb hanging from a drop cord, it sends more power in chosen directions and reduces power in the other.

There. I sed it and I'm glad.

Roy,

Wish I could remember which type it is, but some bypass type ceramics just won't work in a tuned circuit. We never determined why, but think it was because the capacitor value changes with applied votage. John is looking for .11 ufd. He is probably best off with some kind of plastic dialectric cap. I think the ceramic RF caps we all love don't come that big.

Nice analogy Tarmo!

You might note that this one yields noncoherent gain and most of our
antennas yield gain through coherent or "constant phase difference"
addition. So, this one is closer to 1.5dB (or thereabouts).

Not to diminish the analogy though. A picture is worth a thousand words!

I have 2 questions about the orientation of an 80-meter dipole and an inverted V. Planning on a 40-10 beam at 45/50 feet for the other bands.

The ends of the dipole can be running in a north/south direction at about 30/35 feet above the ground.Can I get a semi-omnidirectional pattern, of just east/west?

The ends of the inverted V would be east/west. Peak at about 40 feet from the ground, the ends about 10 feet above the ground. Will this be semi-omnidirectional or mostly north/south?

I don't recall seeing that effect, but wouldn't be surprised at all if the capacitance of a Z5U doesn't change with voltage. I have seen them exhibit "soak" (dielectric absorption), where some of the charge takes a long, long time to make its way out and which makes them appear to re-charge themselves after a rapid discharge or to change capacitance with time. That might be the effect you saw. (Electrolytics also exhibit this effect quite strongly, as does the high-voltage aquadag coating on a CRT. I have very personal experience with the latter.)

X7Rs are relatively free of the strange properties exhibited by Z5Us, and NPO/C0Gs are very stable and predictable. Z5Us should be used only for bypassing or coupling, in places where it won't hurt if the capacitance value wanders all over the place. But don't lump all ceramics in the same category.

The "Z5" in Z5U means that the temperature range is +10 to +85 C. The "U" means that the capacitance can vary from +22 to -56% over that range. By contrast, an X7R varies no more than +/-15% from -55 to +125 C, and a C0G has a temperature coefficient of no more than +/- 30 ppm/degree C. There are other types and combinations, but these or their close brethren are the most common. The temperature coefficient is by no means the only difference between them, though.

Sometimes the temperature coefficient is identified by only a single letter. When this designation is used, "E" means +22 to -56%, "C" is +22 to -33%, "B" is +/-7.5%, and "A" is +/-30 ppm/deg C).

I've got monolithic ceramic capacitors up to 2.2 uF in my junk box. They're Z5U, 25 volts, and about 0.3" square.

Roy,
I have copied your last couple of posts on this topic over to rar+p
where the subject occasionally comes up "what do all those little
letters mean?"
Do you, by any chance, have a reference link that would aid in decoding
them in the manner which you are providing here?
Secondly, any suggestions for divining the voltage rating of unmarked
disc caps?

Tnx,
Bill WX4A/KP4

Chuck, at that height my guess is that you wouldn't get a whole lot of directivity with either antenna...but the dipole should have more directivity than the inverted vee.

If you'd like to get some actual numbers, download the free demo version of EZNEC from http://eznec.com. In the "Getting Started" section of the manual (click 'Help' to access it), it'll take you to the "Test Drive" tutorial. And that takes you through the design of a dipole and inverted vee. They're for 20 meters, but you can easily rescale them to 80 meters by selecting "Frequency" in the main window and checking "Rescale".

1794. Inverted L and Radials

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-02 05:00:05 UTC
From: Pete Ritter <cpritter@attbi.com>
Message-ID: <pZIw9.216259$%d2.72744@sccrnsc01>
Source record: 132032

I want to add radials to my new inverted L antenna. The antenna runs from the ground up the back of the house and then across the roof. The vertical portion is about 9 meters (30 feet) long and the horizontal about 13 meters (45 feet). It is fed with coax through a lightning arrestor which is clamped to a ground rod. The antenna tuner is at the other (rig) end of the coax. I want to work all bands 160(yeah, sure!)-10 if possible.

I can install only 3 runs of radials. Two runs would be 180 degrees apart from each other and the other 90 degrees from those. What would be better?

1. Each run consisting of one wire as long as possible.
2. Each run consisting of one wire of length (how long?).
3. Each run consisting of a bundle of (insulated) wires, one tuned to each band of interest (1/4 lamda?).
4. Your suggestion?

Would I see an efficiency improvement if I were to install an automatic tuner between the coax and the ground end of the L (over that of a manual tuner at the rig end of the coax)?

Thanks for your suggestions and observations.

Pete WB5KLY

Sorry, I don't know of a link. I'm sure it must be Out There somewhere, though.

The tolerance can also be indicated by a single letter, as follows:

F 1%
G 2%
H 3%
J 5%
K 10%
M 20%
Z -20 +80%
P -0 +100%
W +22 -90%

This letter usually follows the value. For example, 223k is 22nF (22 X 10^3 or 22,000 pF), 10%.

I don't know of any similar scheme for indicating working voltage.

Roy,
Maybe I should explain by what I meant by "didn't work". Guy was trying to convert a regular pulse stream to a sine wave, at some fairly low frequency, with an LC tank circuit. The thing tuned very broadly, and amplitude was low and distorted. Just changing to a different capacitor, I think mylar, fixed it. Amplitude came up 4 or 5X. I don't remember the frequency, but it was probably in the tens of KHz.. The original capacitor was one of these black rectangular jobs with leads on one edge. This was a breadboard for a real job, and it was easier to change capacitors, then to figure out why the ceramic did not work. Note that we did not start looking at caps that were not already factory approved.

Both regarded highly by some because the received signal seems louder
than with a 18" whip provided on their particular radio. Really, both
are crap antennas for long-haul DX. If you want to hear Radio Nepal
look into real antennas...if you want Deutsche Welle via Antigua West
Indies, even the AN-LP1 may seem better than an indoor loop.
There's no substitute for pieces of outdoor wire for SW reception.

The full color qsl has to go though the printing press four times, once each for the primary colors of red, blue and yellow, and once more for black. Maybe he's getting a sweet deal on printing, but it ain't normally cheap to send out full color cards, unless maybe it's something he does on a computer with an ink jet printer...

I sent them some sparkplugs they needed about 30 years ago for one of their boats. Got them on a freighter out of New York that was connecting with another going to Hong Kong connecting with another going to VR6.

It took them 9 months to get the plugs.

I don't know if the rules have changed, but years ago it was legal to handle commercial requests from VR6 on the ham bands as that was their major means of communications. I see now they have an internet site.

I recently looked at a web site (MaxComm) that offers a seemingly completely knob-free automatic antenna tuner that can be located anywhere in the feedline. It seems too good to be true. I read the "theory of operation" but could not make sense of it. It used terms and ideas that I have not encountered before. Does anyone have any experience with it, or know anything about it?

It looks like it may be a HyGain 14AVT, but the traps are hooked up wrong.
They are shown upside down from how they would be inserted.

Look up the Boat Anchor Manual site, the manual may be there. www.bama.com
or something like that.

Good luck,

Bill, W4WNT

In short yes, a 3dB gain means you have twice as much signal in the favored direction as the reference.

Next you will receive a zillion answers in here from the folks that will give you the history of clocks rather than give you the time of day you asked for.

"MAXX-COM Antenna Tuners are Fully Automatic."
"MAXX-COM is always tuned and ready to transmit."
"100% Solid State Construction."
"No moving parts to break or wear out."

Because they are simply resistors.
Misleading.

"MAXX-COM is the most compact and
efficient antenna matcher available today!"

Efficient ? Must be about 3dB loss - not good.
Misleading.

"...matches it in 1/1200th of a second."

Or even less...practically instantaneous...
Misleading.

About 3dB attenuation or so, thus 6dB return loss. Although it is a crazy approach, it could actually have practical application in some situations (yachts for example). It rubs against the grain though. Their lack of candor about the technical details is enough to turn off anyone that has seen the X-ray of what is inside.

1817. 144/450Mhz Antenna mounts on Jeeps

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-02 16:35:50 UTC
From: rbraddy@crosslink.net
Message-ID: <c07dab63.0211020835.3e9fec5f@posting.google.com>
Source record: 132056

Mounting an ham antenna on a Wrangler Jeep with cloth tops etc is a challange. I ended up getting a Radio Shack type glass mount antenna and mounted up in the upper corners of the windshield glass. I checked with the local State Police and found it was legal in Virginia if it clears the windshield wiper blade operation. This worked out real good except there isnt much gain associated with this type of glass mount antenna.

I recently bought a couple of higher gain 5/8 wavelength 2m/440 antennas and mounted them on one of those windshield adapter mounts provided by severeal of the Jeep Parts catalog companies that are used for mounting an external spot light for Jeep vehicles. These mounting plates mount over the existing windshiled hinges and give just enough room for the motorola type NMO mounts. The antenna cable runs down to the gap in the windshield hinge and right into the vehicle compartment around a rubber thing used with the jeep doors. The cable is barely visible from the outside... Pretty neat installation...

(1) In using Type 77 ferrite beads on coax as an HF choke, is it
better to use four small 1/4" long beads or one large 1" long bead
(multiplied as necessary)?

Is it better for the beads to touch each other, or to be separated
(say by hot melt glue or othe non-conductive material)?

(3) If it doesn't matter, isn't it better to separate the beads for
better cooling?

> ...MaxComm...

"CAM"
> You're right, Steve, a dummy load doesn't have any knobs.

To be completely fair, it isn't THAT bad. It should radiate about half the power fed to it (excluding other system losses). A good (well shielded) dummy load would obviously radiate much less.

For a yacht, being 3dB down in output power might be made up by the wonderful salt water ground plane of the ocean. And on receive on HF bands, efficiency isn't usually a concern since the S/N ratio is usually set by the external environment anyway (simply twist the RF Gain a bit). A yacht seems like a reasonable application. Especially if the sailor isn't interested in fiddling with tuners.

It's too bad that their marketing approach is so misleading. "Solid State" and all those other half-truths. I think that they could actually improve their sales by being more open about the not-so advanced technology being employed and honestly explaining the trade-offs.

1820. Pattern of *Tri-Di-Pole*+++

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur,rec.radio.amateur.homebrew,rec.radio.amateur.dx

Could use some help from some of our more technically minded antenna buffs.

Several years back, I came up with a general use dipole for SWL's that I named the "Tri-Di-Pole". The "Tri" meant a third wire element connected to the ground side of the dipole at the appex, with this wire running straight done to be connected to a ground rod. This was invented more for practicality purposes, so SWL's didn't have to fiddle with ground wires soldered to those tiny little external antenna phone plugs that are in common use for most portable shortwave radios.

But over the years, several hams have called me about using this same antenna for transmitting. To be honest, I've never tried it for transmit. I just don't have the real estate to experiment with it. But now I'm curious, how well would it work for transmitting purposes?

My devices are born more out of a practical design than technical. I freely admit I'm not all that antenna theory book smart. My questions: What kind of a pattern would this antenna have? Would the take off angle make it highly suitable for DX on certain freq bands? And what would I have to trim? Just the two standard dipole elements? Or would I also have to trim the third ground element? Anybody ever try such a design for transmit and on what freqs?

Thanks for any/all input.

Steve,
This thing was first marketed in the early 80's, so
I guess at least part of the advertisement is true.
There were a number of them sold, mainly to people on
boats, and some of them even had good things to say
about it (you can imagine how bad their antenna system
must have been). One of the magazines had one of the
'Maxxcom' tuners X-rayed and found that it was a circuit
board and a resistor, with a few other random parts in
the potting material. After that article was published,
Maxxcom sort of dissapeared. I'm suprized to see them
back...

Let's say you are using one with a one wavelength dipole that has a feedpoint impedance of 6000 ohms. How are you going to radiate half your power? Seems you are talking about an antenna that is already nearly resonant and using the MaxComm for broadbanding. If that's what you are talking about, I agree. That's essentially why a double bazooka is broad banded.

> For a yacht, being 3dB down in output power might be made up by the
> wonderful salt water ground plane of the ocean.

You seem to assume (without proof) that it will radiate half the power and then say radiating half the power is not too bad. It will not radiate half the power when it is used with an antenna with a feedpoint impedance of 6000 ohms or one with a feedpoint impedance of 10-j1000 ohms. The range for which it will radiate 1/2 or more of the power is pretty narrow.

I have a Inv-L for 160 and have 3 radials. Two of them are
about 80+ feet long and the other is about 40 m.
Don't worry about the length just put down at least 3 mostly
under the horizontal part of the L.
Don't worry about it. Mine works great. Sometimes 2-3 S-Units
better than my R5.

Pete Ritter wrote:

> How are you going to radiate half your power?
> <etc. - snip - refer to original if req'd.>

Your point is valid - I was thinking about reasonable antenna lengths and reasonable feedpoints. Obviously the ~3dB attenuation would have to vary with antenna feedpoint impedance. This could be analysed and plotted I suppose. I wonder if they have already optimised the design in this respect ? ...nah, not likely.

A real antenna tuner is obviously better than a maxcomm. I'm still of the opinion that a maxcomm would be better (for some applications) than no tuner at all. A yacht seems a likely example where it might be a 'reasonable' tradeoff.

Their marketing approach is very discouraging to those that know what is inside the box (resistors). It is hard to support the product due to the misleading statements.

If it is from the 1980's, then I suppose the patents (if any) must be just about up. Perhaps someone could start marketing a similar 3dB attenuator with more forthcoming marketing information on the technical details and tradeoffs.

Electrically it doesn't matter.

> (3) If it doesn't matter, isn't it better to separate the beads for
> better cooling?

If heating is a problem, yes, separating them should improve the cooling. It there's still too much heating, go to type 43 ferrite and increase the number of beads to compensate for the lower impedance.

I just went to the Fair-Rite web site http://www.fair-rite.com to get you a number, but it looks like they've presently got a hacker problem. I have some information on an older type, 73, but it's similar to 77. To get the same impedance with type 43 material that you'll have with type 73, you'd have to increase the number of beads by a factor of nearly 3 at 3.5 MHz, 2 at 10 MHz, or 1.2 at 30 MHz -- or a factor of about 3 to have at least as much impedance over the whole HF band. Which is why I recommend using 70 series ferrites if you can.

Jack,

I have one. It's a nice little box...especially for the price...but you must use a good ground or counterpoise otherwise rf will lock up the micro-processor. It's an unbalanced device by design...so if you need to use it with a balanced antenna, you need to isolate both the feedline and power cable with chokes.

They recommend unbalancing antennas like dipoles by making the "cold" side 5% longer. Loops are another problem...you'll need some kind of counterpoise.

For my application of feeding the driven element of a minibeam...I had to make my own tuner, since I didn't want to skew the pattern by unbalancing the element. I chose to put only coils, caps and relays at the antenna, and put the processor in the shack.

I am planning a future article describing my tuner, which uses a standard computer as the processor and controls the tuner through RS-232.

If your need is for a balanced antenna, and you don't want to build anything, you might want to look at http://www.hamware.de/hardware/tuner402/at402-e.htm . It's a German company that uses an approach similar to mine as far as keeping the electronics separate from the tuning elements, with the added advantage that it is totally balanced.

1830. Re: What'e your favorite method to bring coax into the shack?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-02 20:31:26 UTC
From: rbraddy@crosslink.net
Message-ID: <c07dab63.0211021231.5ab9f4c2@posting.google.com>
Source record: 131969

I installed a 6"x6"x4" water tight plastic box (from Lowes) on outside wall about 3 feet off the ground... Then on inside wall I installed two recessed wall boxes with blank panels on them... Then I installed six type "N" bulkhead connectors in the outside box and three on each of the two inside boxes and connected them together with RG214 cable.... It was real easy fishing the cables between the inside and outside boxes... The outside box lid has a piece of aluminum on the inside lid held in place by the bulkhead connector nuts. I run this to ground rod next to the easyup pipe... Now all my antenna leads from various roof mounted antennas come down one easyup pipe running up the side of my house next to the 6" plastic box and I have all the cables tie wraped to that pipe.

This hides all the ugly cables down the side of the house and gives me an outside ground point as well... On the inside I just run a RG214 cable from the inside wall mounted boxes to my equipment. I use right angle type N adapters to keep the cables close to the wall.... They can easily disconnected as well if you start worrying about thunderstorm...

Looks neat also...

Larry,

Many tnx for the reply to my post. I will use the tuner in my camping trailer with a random length of wire50 or more feet long.
There is a 3-ft length of RG-58 between the back of the rig (TS-570SG) and a UHF bulkhead connector through the wall of the trailer.

I will mount the tuner outside of the trailer so that the wire antenna will connect directly to it and use at least two counterpoise wires as per the instructions.

Since I am putting the trailer away for the winter, it may be March(!) before I get back to this project.

tnx es 73, Jack

Sure looks like the Hy-Gain 14AVQ that I used to have. The manual can be
downloaded at:

http://www.hy-gain.com/hy-gain/man/pdf/AV-14AVQ.pdf

Hope this helps.

Get an old garden hose. Cut the ends off and feed the coax through it.
I have not done this for the whole length of a roof, but have used short
chunks split and retaped around the coax for going over roof edges.
Never had a bit of problem with them.

Think up side down. Feed your new antenna at the top in the center so you
have one half running horizontal and the other half vertical. You won't
need radials. Feed it with ladder line if you want to work all bands.
Check out http://www.cebik.com/ltv.html and
http://www.cebik.com/gup/gup26.html

CAM, W5DXP wrote:
"Unfortunately, the conjugate matching theorem only aplies to linear systems and we cannot achieve more than 50% efficiency without non-linear amplifier sections---."

Transmitter output is reasonably linear. It must not be too non-linear because high-harmonic content is outlawed by regulations. Non-linear signal generation elements may be and must be combined so as eliminate distortion. Another way to avoid distortion is to filter the distortion out after it is generated.

A "Class B amplifier" often uses two non-linear devices in a combination which avoids distortion.

A "Class C amplifier" often elimnates distortion created by its efficient part-time operation by following the amplifier with a filter which screens out harmonics. The high-Q tank circuit is an example.

I got myself some 1.5" EMT pipe at the hardware store and one of those turtle-shell type caps that they sell for bringing electrical cabling into the house. A few minutes of sawing later I had a hole in the roof through which I put the EMT, securing it internally to the rafters and creating the entryway into the shack. Then I simply installed the coax as if it were electrical cable.

Can't say bringing coax into the shack like that will do much for lightning protection though. I figure it's acceptable in my case, where lightning storms are infrequent and I have a couple of "more likely" targets nearby. Your mileage may vary.

Hello. I am working on learning the code, so I am also starting to look for an affordable HF antenna. I currently have a G5RV that will be going up when I find the time. I was also thinking of putting up an HF vertical with as many bands possible. I can install in on my roof with no problem. Can anyone make some recommendations as to what antenna I may want to consider. Something that doesn't require radials would be perfect. I live in NJ, so it would have to be able to withstand the occasional harsh winter and hurricane/tropical storm. We usually have at least 1 severe storm per year with high winds and heavy rain.

You lose 3 db each time you split the signal. If you have good strong signal coming from your antenna there should not be a problem. For best results use a splitter made for this purpose (Radio Shack, etc).

The proper way to do this is with a power splitter, commonly known as a "two-set coupler" or a "multi-set coupler". These can be purchased almost anywhere electronics are sold. Radio Shack, Best Buy, Cicuit City, etc.

Of course you do not get something for nothing; the available signal is shared between TVs and some more is lost in the coupler itself. If you have signals that are strong enough to begin with, you will have no problem. If the signals are already marginal, then they will be much worse, and the solution is an "amplified splitter" or a "distribution amplifier."

Bill,

The quick answer is yes, the signals will show a slight
directivity in the direction of the tilt.

But what is more important is the height of the antenna
above ground in wavelengths. If your sloping dipole is
at one wavelength or higher above ground the effect will
be more pronounced. But, a fifteen foot difference from
end to end is not going to affect it much either.

So the answer I guess, is: It depends! Put that rascal
up and see what happens!

Bill,

You gotta tell us how long the antenna is. If it is a160m antenna - no. If its a 10 m antenna, you got yourself a vertical.

There's the possibility of interference. Go to Radio Shack and buy
yourself a 3dB splitter for isolation between the receivers.

Dear Friends,

due to some restrictions, i'm not able to have a "big" antenna on
the roof. Therefore i would like to buy two antennas, which i
could also use as mobile.

1. AP-10A by Barker & Williamson.
2. Buddipole by W3FF Antennas.

They will be used at the first step for reception of 14 - 28 MHz
and
sporadicly CB qso's.

Does anybody have experience with any of this antennas and what's
the opinion like?

Best regards & 73

There is no damage to come from connecting 2 or more TV's to one single antenna. The only problem will come from the strength of signal because you do not respect anymore the impedance of the antenna in putting TV receivers in parallel. Consequence: possible noise (snow like) if signal is weak. Solution if signal is strong enough: a splitter.

1868. Re: multi strand wire vs single strand copper?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-03 22:31:30 UTC
From: R P Haviland <bobh@iag.net>
Message-ID: <6thx9.760$l8.102883@newsread1.prod.itd.earthlink.net>
Source record: 132006

Stranded wire is less likely to fail mechanically than a solid wire of the same area. The reason is that a crack can start to propagate from the surface. In a solid wire, it goes through the entire wire, for failure. In stranded wire, it goes through a strand, causing some loss in strength, and shows on inspection. Try it by bending both types across a corner a number of times.

Source record: 132007

Insetad of trying to model the fine details of an antenna, try the
following:
1: Get the perormance you want with average element diameter, at design
height and best guess ground
2: For each element without the others present, find the resonant frequency
3: Build the elements, tapered, hose clamps, mounting plates, etc
4. One at a time, mount the elements on the boom, and measure the resonant
frequency with a grid dip meter coupled to the element, inductively near the
center, a very small capacitor near the high voltage point, usually the end
6. Adjust the element length to get the same resonant frequency as in 2,
repeat for all elements
7. Mount the elements.

Performance will be as near to calculated as you can get. Major difference
will be the difference between calculated and actual ground conditions

Anybody have any experience with this antenna? I have been thinking of putting one on 80 meters via stealthing it in a tall pine tree. However, I just read an article by a fellow who contends that the broadband characteristics of this antenna is due to the large resistive losses inherent with this type of antenna. As such he says it is not an efficient radiator. This being said, I have picked up a few articles on the net from some qrp operators that say the antennas works very well....What gives ?

Ersoy,

I have used the AP-10A on 10 and 15 meters with good success. It is light and compact and installs and tunes easily. It is however, somewhat fragile and care needs to be taken when handling it. It does not perform as well as a larger antenna mounted high in the air, but you will make contacts with it and be able to monitor as well.

>Anybody have any experience with this antenna?

I have never used one, but I have read quite a bit about them, probably the same article you read. The increased bandwidth is due to lossy resistive loading. The losses result in a less efficient radiator compared to a simple half wave dipole.

If I were going to use resistive loading to increase bandwidth, I would just put a suitable resistor at a half wave dipole feed point. Get the same results as a bazooka, but without all the coax and open wire (ladder) line up in the air. Finding that resistor may not be that easy though.
>some qrp operators that say the antennas works very well....What gives ?

A bazooka may make your 1 watt qrp rig sound like a 600 milliwatt rig using a standard dipole. But you could still say my bazooka antenna works very well, but compared to what? A bazooka would be very visible. If it is Stealth you are after, an 80m dipole made with #20 stranded wire insulated with your favorite color to blend in with the background ought to work.

Thanks for all the replies. It was kind of a theoretical question. I
had a fan dipole arrangement up with one end higher than the other,
but I figured that would be too complicated to try and figure out.
Friday I managed to get the lower end higher up in the tree so that
it's now level. Yesterday, I worked 5Z4DZ on 17 meter SSB running 100
watts, so I guess it works.

Mike,

If you are trying to cover all of 75/80 meters, you might want to consider a pair of crossed dipoles fed from a common coax. I never built it, but according to EZNEC simulation, a dipole of 118 feet, and a dipole of 132 feet from a common feed point should have less than 2:1 SWR from 3.5 to 4 MHz. (@50 ohms). I know 118 feet seems short, but there is interaction between the two dipoles. I did not try angles other than 90 degrees, but my guess is that something like 30 degrees might work. The nice thing about 90 degrees is that there are no real nulls.

There's a half truth there. There are not "large" resistive losses in
a Bazooka. At the resonant frequency, it is about 95% efficient compared
to a dipole. You can hardly measure the difference in performance and
you are not likely to see any difference on the S-meter. But the Bazooka
bandwidth is usually overstated and is only about 1.14 times a simple
dipole. IMHO, a Bazooka is simply not worth the hassle.

Keep the ladder-line at least 4 inches away from anything except
insulators. You will lose energy if you lay it on the ground.

Have you checked prices on these small fixtures at those sources lately?
Even at dear old Walmart they're outta sight, IE three bucks for four RG59
"F" connectors, with all the other pieces also priced way up there. A few
days ago when I wired up my daughter's satellite TV system I wound up
buying all the stuff at Home Depot. For example I got ten F connectors for
a third less than the four at Walmart.
It makes sense. Home Depot sells in bulk to lots of contractors who
nowdays wire up new houses for all the home entertainment and computer
needs of the modern family, and contractors are usually price conscious.
To the other retailers this is "convenience" stuff and is priced
accordingly.

1886. Extracting Reflected Power

Date: 2002-11-04 05:29:00 UTC
From: CAM <Cecil.A.Moore@ieee.org>
Message-ID: <3DC6059C.DBCB2DBF@ieee.org>
Source record: 131924

I recently had an email interchange with someone associated with QEX
who believes reflected power cannot be extracted from a transmission
line. This is obviously an old wive's tale. Consider the following
recently used example:

100w XMTR--50 ohm coax--+---1/2WL 150 ohm feedline---50 ohm load

On the 150 ohm feedline, the steady-state forward power is 133.33w
and the reflected power is 33.33w. All one has to do to extract
the reflected power is switch the load to 150 ohms. In the length
of time it takes to clear the reflected energy from the 150 ohm
feedline, that reflected energy will heat up the 150 ohm load to
the tune of 133.33 watts, for a short time, more than the output
of the transmitter.

Of one wants to visualize this experiment in a human time frame,
make the 150 ohm feedline one second long. Then, for two seconds
after the load is switched to 150 ohms, the 150 ohm load resistor
will dissipate 133.33 watts or a total of 266.66 joules of energy
while the transmitter is putting out only 100 watts.

|needs of the modern family, and contractors are usually price conscious.

I don't know about F connectors at HD but don't assume for a minute
that because they sell to contractors they are the lowest cost vendor.

I did a substantial addition to my house and did a lot of comparison
shopping. I didn't buy much at HD.

Another yard set me up as a contractor and made a quote upfront. At
the time, No2 BTR Doug fir 2X6X12 were $5.12 each. They were about $7
at HD and the other guys kept giving me the quoted price when I went
back for more even though the price got as high as $8. (Like
gasoline, lumber prices change on a daily basis and a real yard
charges their replacement cost + markup)

Similarly copper pipe and fitting were 25% higher at HD that a local
plumbing supplier. Copper wire was about 40% lower at a local
electrical supplier that caters to DIY.

This will only get worse as HD puts the smaller guys out of business.

For the record, for cable operators who obviously buy in bulk, the
cheapest of cheapo F-connectors like you find at retailers cost about
6-10 cents each. Two-way splitters of the same ilk cost about a
quarter. Decent RG-6 about 6 cents/ft, Quadshield RG6 about 12 cents.
Point being that you can often beg of your DSS or cable outfit to sell
you what you need for proper wiring and they may well be the cheapest
option.

This discussion came up awhile back with a group around here where I live. How does one explain, in laymens terms, or using an analogy of how a simple yagi antenna works? (for purposes of discussion, we will consider a simple 3 element yagi.) I and the others (as well as many here) can explain how it works in a technical manner, but none of us can explain it in the simple manner. Take this as if you were trying to explain this to someone who does not have much knowledge of radio theory, say for instance, like your grandmother or an aunt somebody like that.

Like I stated, I can explain it in the technical manner, but am trying to figure out how to explain it to average person with little to no radio theory experience...

Thanks,

> reasonable feedpoints.

"reasonable" is in the eye of the beholder. I think Cecil's
one-wavelength dipole is a very reasonable length. I'd put the
feedpoint Z at around 4000 ohms rather than 6000, but that's a minor
point.

>Obviously the ~3dB attenuation would have to vary
> with antenna feedpoint impedance. This could be analysed and plotted I
> suppose. I wonder if they have already optimised the design in this respect

The thing has two major components - a three-winding toroid and some
big resistors. The fact that they don't even specify the alleged
patents tells you something.

> tradeoff.

Maybe, but consider this example:

Boat with 33 foot backstay
Ham who wants to check into 20 meter maritime net
Feedpoint Z - about 1200 ohms

With a nice saltwater groundplane and a simple tuner, such an antenna
will be almost 100% efficient. What's the efficiency with a maxx-com -
4%? That's about 2-3 S-units of difference.

I don't know if this unit has any connection to the original Maxcom
units reviewed in QST. Those units cost a lot of money - more than the
automatic SGC tuners do today, I think. Much more than CAM's "linear
tuner" idea, too. They included a scrap printed circuit board inside
the epoxy potting, btw.

They've even got competition from the "Match-All" unit.

I.e. the current in the radiating element induces a current in the reflector just a few distance away. This current produces at its turn an electromagnetic field. To improve the overall gain, the reflector is placed in a position for which the two EM fields (radiator and reflector) will add in phase at long distance and in the plane of the yagi. same with director. But a bit too simple.

1898. How does a tuner match parallel dipoles?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-04 15:15:13 UTC
From: kiddi@marel.is
Message-ID: <b7cca008.0211040715.58873cf4@posting.google.com>
Source record: 131937

Hi:

I am considering putting up an inverted-V, consisting of parallel-connected dipoles for 10, 15, 20 and 40m. It may be optimistic to think that I will get a low SWR on all these bands, fed with a 50 Ohm coax through a balun. So, if there will be a (hopefully minor) mismatch, I intend to use the internal tuner of my rig to help bring the SWR down if needed.

Now, here is something I wonder about: Will the rig tuner necessarily accomplish minimum SWR by matching to the antenna that was "intended" for that band? For example, I may be operating at 28MHz, but I suppose the tuner may take control and find a match to the 7MHz wires. In that case I am not having the intended radiation pattern that I was expecting from the 28MHz dipole wires, but rather having another (less desirable) radiation pattern of 28MHz currents running in the 7MHz wires.

Does anyone have a comment?

Source record: 131958

I'm basically following the discussion and am happy about the concept
applied to directional antenna but how does it apply to vertical 'sticks'.
From what is said the gain figures for vertical whips etc quoted in all the
adverts are meaningless. The only reference I can think of would be a single
full wavelength antenna and my 1/2 wave, claimed to have a gain of 3.5 dB is
approx twice as good a the full wavelength one would be. Have I got that
right?

Given that antenna (passive) can't amplify, and are less than 100% efficient
due to losses, I would have thought that the 'gain' would in fact be
negative.

Musta' been.

Cecil touts more reflected power out than is put in, but only on a
transient basis.

How about an example where there is more reflected power output than
input on a *continuous* basis?

Consider this. An ideal three-port circulator has ports one, two and
three. Being 'ideal' it has zero loss and the direction of signal
propagation is from one to two to three and back to one. There is no
leakage in the opposite direction. Power applied to any port rotates
to the next port where it can be 1) totally reflected, 2) partially
reflected, 3) totally absorbed, all depending on the reflection
coefficient of the terminated port.

Power reflected from any port propagates on to the next port. Thus,
the circulator acts as one type (along with directional bridges and
couplers) of "signal separation devices" that are the backbone of
reflection coefficient measurement systems.

If we apply input power to port one and install a perfect short
circuit to port two, (reflection coefficient = 1 <-180 deg) *all* of
the power is reflected and travels on to port three. If we install
the elusive *perfect* termination (reflection coefficient= 0) to port
two all of the power is dissipated and none travels to port three. A
load on port two with a reflection coefficient between 0 and 1
produces power at port three that is a function of the reflection
coefficient. Thus, by measuring the power at port three, the
reflection coefficient of the load on port two can be determined.

We can "calibrate" this system by installing at least two different
known terminations in turn, 1) a perfect short circuit, 2) a perfect
termination and measuring the power at port three.

NOTE TO THE JANITOR'S WIFE: The power appearing at port three due to a reflection on port two is *real* (actual) power, it is not imaginary or fictitious power.

The complex reflection coefficient, gamma, is found from:

gamma = (Zo - Zl) / (Zo + Zl)

where Zo is the system impedance and Zl it the impedance on port two.

Our simple power measuring system can't measure phase so let's assume that all values are purely resistive and set Zo to 50 and Zl to -10 ohm.

Solving the equation gives gamma = 1.5. But during our calibration, a full-scale reflection measured 1.0. We have a greater than full scale indication, thus there is more reflected power output than incident power input.

Now if I could just find a -50 ohm resistor, I'd be rich.

The problem can occur if you have a 40m dipole and a 15m dipole. A lot
of hams just use their 40m dipole for 15m and omit the 15m dipole. The
problem you are envisioning should only happen at 1/2WL, 3/2WL, 5/2WL,
etc. It's not likely to happen with 40m, 20m, & 10m dipoles. Try omitting
the 15m dipole and trimming your 40m dipole for resonance on 15m.

> transient basis.

Not exactly true, Wes, more reflected power out than is presently being put in. The excess power was put in during the initial transient build-up process. We cannot use reflected power for impedance matching purposes while at the same time extracting it. But we can indeed extract it once we stop using it for impedance matching purposes.

> How about an example where there is more reflected power output than
> input on a *continuous* basis?

No problem, Wes. Here's a quote from "Wave Mechanics of Transmission Lines, Part 3", Nov/Dec 2001 QEX. "... the forward source power of 92.831 W combines in-phase with the re-reflected power of 0.555 W, resulting in a total forward traveling power of 107.736 W." Tap off the excess 14.35 watts to run a flashlight and return the other 92.831 watts and 0.555 watts back to the system. How's that for an example? Where else can you find vector math that allows the sum of scalar components to be greater than the sum of the absolute values of the individual scalar components?

> Now if I could just find a -50 ohm resistor, I'd be rich.

How about a tunnel diode? delta-V/delta-I is negative. :-)
But watch out, it might create a black hole. After all, that excess 14.35 watts above needs another universe to flow into, hopefully the same one it flowed out of.

1904. Re: How does a tuner match parallel dipoles?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-04 16:27:15 UTC
From: Tarmo Tammaru <t-tammaru@home.com>
Message-ID: <lpecncoDQ4MEAlugXTWcpQ@comcast.com>
Source record: 131942

Kristinn,

I have 3 dipoles, connected to a single balun, at 12, 17, and 40 meters. The SWR is very good without a tuner. If at all possible, run EZNEC on your proposed arrangement, because there is interaction. Also, when you go to tune them, you have to adjust the LONGEST DIPOLE FIRST. In my case, the length of the 40 m dipole has a large effect at 12 and 17, whereas, the latter two have almost no effect at 40 m. You need a lot of separation between the ends of the dipoles; around 5 or 6 feet will work. You can also have them out of plane. I have the 17 m dipole as a V, which supports the whole thing, the 12 meter ends up being horizontal, and the 40m is an inverted V - out of plane with the others. (Trees are too close together to hang a 40m dipole between them. The 17m dipole is a V, because of sag). There may be a problem having dipoles that are harmonically related.

Source record: 131943

Wes:

[snip]
> NOTE TO THE JANITOR'S WIFE: The power appearing at port three due to
> a reflection on port two is *real* (actual) power, it is not imaginary
> or fictitious power.
[snip]

I thoroughly agree with you that the power transmitted from port one around to port three, of which you speak, is in fact a real power and not, i.e. ficticious.

However, the power appearing at port three is *NOT* reflected at or from port two! That unfortunate *word* description does not clearly describe circulator dynamics rather it obfuscates.

Expressing reflection phenomena in *words* often leads to misunderstandings of the actual facts and methods of operation and is simply the unfortunate effect of the symantics [English language description.] commonly used to describe reflection mechanics.

In fact *that power* emerging at port three is not a "reflected" power at all, rather it is a "transmitted" power. It is in fact the forward power transmitted by the circulator from port one past the port two and out port three.

Using English *word* [Or any language] constructs to describe reflection mechanics is often fraught with such ambiguities. Unfortunately the whole field is rife with such symantic difficulties. Instead... to gain a deep understanding of reflection mechanics bereft of the ambiguities which have grown up around the common word descriptions of such phenomena, one must examie mathematical descriptions or examine actual schematic diagrams of the devices/systems both methods which offer an unambigous view and understanding of the underlying phenomena.

Since mathematics is arcane, electrical or electronic schematic diagrams present a more comfortable view for the engineer/technical person. This is the case for myself, even though I understand and can perform all of the mathematical manipulations of reflection mechanics, my "gut feel" for reflection mechanics comes from examining schematic diagrams labeled with currents and voltages indicated thereon. I can then *see* where the electrons are going next so to speak.

Now unfortunately a schematic diagram for a *microwave* ferrite circulator is not very illuminating, since the internal circulation mechanics for those ferrite devices operated at microwave frequencies are intra-material and are not actually shown on the schematic. This is another unfortunate situation

that adds to the mystique. Most folks would understand things a lot better if they could *see* the circulator actually circulating at DC!

To understand the circulator operation in detail it is best to study the shematic diagram of an *electronic* circulator, not a microwave ferrite device.

Such an *electronic* circulator schematic in its' simplest form consists of only three operational amplifiers arranged in a "ring" together with six resistors. Most folks when they first see this schematic are amazed at the simplicity of the circulator operation, and it even works at DC!

It has been my experience that after examination of the schematic of even the simplest active electronic circulator shematic most "techies" hit themselves on the forehead in the Italian way and say, "so that's how it works, there is no *reflection* of power involved at all, why didn't I see it before".

It's too bad that *electronic* circulators are not as widely used as *microwave ferrite* circulators. In fact although one can purchase a microwave circulator as a complete device, one cannot [at least to my knowledge] go out an purchase electronic circulator. Instead one has to make one, it's simple though since it's only made up of operational amplifiers and resistors and electronic circulators are very easy to build, test and observe and they work from DC, all the way up the upper limits of the operational amplifiers bandwidth capabilities. I myself have built tens of them myself and have put tens of thousands of them into production designs.

Observing, with nothing more than a simple VOM, the operation of a circulator while it is circulating DC power is plain downright illuminating.

For indeed, where are the so-called "reflections" at DC [zero frequency]?

Hi Peter,

I think Wes was pretty concise and far from obscure. If you knew nothing about electronics at all, and were to accept it as magic it would still make sense. I am sure your DC circulator is as useful, but you chose to talk about its utility rather than its design. I am familiar with the implication of 3 Op Amps and 6 resistors, but few in the general readership would be (the topology is missing).

So to your point of fighting obfuscation, I would offer that Wes stands out there ahead of you. Fewer claims and more details for all, please.

Reflected voltage requires a delta-V. There are no delta-V's at steady-state DC. There certainly are delta-V's and reflections during the buildup to steady-state DC. Where is the so-called "current" on a capacitor during steady-state DC? Is current on a capacitor imaginary? If so, why can't we can throw away all our caps?

Cecil,

I never worried about this, and am not sure what this proves, but you might want to look at passive telephone echo cancellers and hybrid transformers. They actually unbalance these slightly so you can hear some of your own speech (sidetone). You certainly hear the other guy, and any echo on your own signal.

When I was working at Intel, we had some connections to the Far East
that were so bad the reflections made communications virtually impossible.
Of course, those reflections only existed in my imagination but I sure
seem to have a vivid imagination. :-)

I am modeling a 1/4 wave vertical 10 feet about ground with 4 radials.
I was wondering what the efficiency is for the antenna.
Is is it comparable to being 1 foot over salt water?

From what I have read it is susposed to be real efficient.

Thanks for any input!

Jeff

Cecil,I looked at my standard programming collection and I saw that
a 2 element beam can exceed 10 db gain.If the amateur comunity cannot
fix its own problems can you blame a business man for opting for the
highest figure of gain, a main factor of interest. We stand silently
when the newcomers to the hobby declare that 'TRI" as in tribander now
refers to number of elements.
Soon I expect that these types will add 'dy' to the term 'dx' to
signify
that dy/dx means an antenna capable of radiating to another country.
It is this
that I am driving at with respect to putting our house in order
otherwise a skilled debator can spread disunity thru out the hobby in
a malicious way.
Art

Roy I thank you for your invitation to disclose how the state of the
art or the envelope has been pushed out further.I have already been
fortunate this year to finally extract acceptance of the reality of
some of the possitives of my antenna when Clark was unable to debate
the truth away regarding multi band use
and actually congratulated me which does not mean anything because it
has tsaken 10 years to overcome a naysayer that is more interested in
debate rather than the truth.Now he continues the debate not only
because we do not have our house in order and he has seen a model that
he cannot refute he is able to take advantage of our disarray
regarding 'What is gain' .It has been said one
Forgive them Lord for they know not what they do" which is intended
for followers who enjoy the merth of seeing the dificulties of
others.This is not meant for those who choose to debate, lie, or what
have you for his own reasons.
Until we get our house in order these arguments will continue into
perpetuaty
especially when modelling programs which now of great interest
provides a 10 db figure of gain for two elements brings forward such
wrath.
I will take up the question you posed with respect to the atributes of
my antenna, but after ten years of trying delay, at the moment is not
going to hurt.
Obviously after reading 'What is gain' time will be better spent in
explaining
how this disorder was created in the first place in a posting directed
at you
as an engineer where I will show you and other intelligent people how
ignorance of history is having an effect on our hobby today.
Hope you had a good weekend with the contest,my weekend was used to
full fill the wishes of my wife in return for antenna time that I have
taken.
Regards
Art

Since you didn't tell us the frequency, nobody will be able to answer
your question. If it is 1/2WL in the air, it will perform pretty well.
If it is 0.04WL in the air, it will perform rather poorly.

"10 db" over what?. The lowly 1/2WL dipole can achieve 8dBi gain over average ground. Adding one element should increase that to 11dBi over average ground. A two element beam with only 10dBi gain over average ground is less gain than a standard 2-element beam. There's no magic or supergain in the hexbeam. It fits right where it should in the overall scheme of antennas and has some mechanical advantages to boot. There is no need to exaggerate its capabilities.

Many vertical antennas, especially at the higher frequencies, use linear
end-to-end phasing to achieve gain. If the antenna is made wavelengths long
with phasing coils in between the radiating elements, one can achieve a
flatter doughnut pattern. My 2x4MAX is supposed to have 12dB gain over
a 1/4WL vertical on 70 cm, i.e. a very flat doughnut shape that multiplies
the power by 16 times the ground wave of a 1/4WL vertical.

Roy, Art didn't say 10 "dBd". I think we can safely assume it is 10 dBi
over ground, the same gain my 80m dipole achieves on 10m and also the
same gain a 10m EDZ dipole will produce over average ground.

If you're interested in building your own, I have a design that is resonant on 20, 15 and 10 meters, without traps. I've never tested it on 12 or 17m, but I'm sure that at the very least it would be ok on those bands with a tuner. It does require radials but it's not super tall (3.5m) nor are the radials super long (also 3.5m).

Hi Andy, I just bought the GAP Titan DX, it covers 80 thru 10 meters. It does NOT require radials. Presently is is laying on wooden saw horses and it receives quite well. I will be putting it up toward the end of the week when the weather is much nicer. I am going to ground mount it for the time being, if I feel I need more distance I will place it on a 20' heavy wall pipe.
It weights 25 pounds and it 25' long, it's easy to assemble. You should be able to enjoy the greater majority of the bands.

Sorry for the top posting, I was there and just began typing.

73's

1927. ??Constructing an external antenna for cell phone??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-05 00:02:07 UTC
From: Mark <mhopkins@iei.net>
Message-ID: <ek1esugqgphpathdbkfe5p5h1a7b94nlgr@4ax.com>
Source record: 131870
Cross-posted to: alt.cellular.motorola,alt.cellular.tech,alt.cellular.verizon,rec.radio.amateur.antenna,rec.radio.shortwave

I found this "pin out" diagram for my phone:

Motorola StarTAC butt plug Pin-Out diagram

I assume *NO* responsibility
1) GND Connected with 22pf to pin 3
2) RF out
3) GND Connected with 33 pf to pin 8, 33 pf to pin 1, 33 pf to pin 7
4) BAT_FDBAK
5) MAN_TEST connected with 10k to L275
6) RS232_TX - connected to MCU SPI bus
7) RS232_RX - connected to MCU SPI bus
8) AUDIO_IN
9) AUDIO_OUT
10) GNDA (Ground reference) Connected with 33 pf to pin 13, 33 pf to pin 14
11) UPLINK -|
12) DOWNLINK -|- DSC bus connected to the BIC
13) DSC_EN_B -|
14) EXT_B+
15) GND

But I don't understand where to solder the coax shield?? Do I just connect it to the ground?? For that matter, why can't I just unscrew my cell phone's antenna and stuff the coax into the phone in its place (crude I know)?!?!

I was also wondering about the antennas for cordless phones; I know it's against the rules to add an external antenna to my 2.4 GHz phone base but, (rhetorically speaking) how would you ground the coax shield on a phone with just a "metal stick" for an antenna (if you were going to -which of course I am not)?

The background for my project:
A bunch of my buddies and I go camping in rural Southwest Indiana at a friend's "weekend property". Nobody can get cell reception there, but 2 miles down the road everything is fine. So, I bought me an antenna book and have constructed a small ground-plane antenna for 800 MHz (Verizon) use, and I am going to stick in a big-old tree out there in the woods to see if we can get reception (when we want it).

Thanks,
Mark

Question:

>Where else can you find vector math that allows the
> sum of scalar components to be greater than the sum of the absolute
> values of the individual scalar components?
>

Given that the question is directly related to determining the scalar power that results from the superposition of two vector voltages the answer is: In every basic electric circuit text book that discusses the concept of superposition and power.

When two vector voltages, V1 and V2 superimpose, the total vector voltage, VT, will be equal to the vector sum of V1 + V2. The total scalar power that results from the vector sum of V1 + V2 will not be equal to the algebraic sum of P1 + P2 unless the vector voltages V1 and V2 are 90 degrees out of phase. If you are dealing with only the scalar powers P1 and P2, the total power that results from the vector addition of V1 + V2 will be given by P1 + P2 + 2 Sqrt(P1) Sqrt(P2) Cos(T), where T is the phase angle difference between V1 and V2.

The vector math that Cecil refers to in the quoted QEX example relates to power and voltage. The |VT| which is equal to |V1+V2|, will not be greater than the sum of |V1| + |V2|. However, the scalar power, which is a function of |VT|^2 (or |V1 + V2|^2) can be greater than the sum of the individual powers P1 + P2. From a vector perspective, this is equivalent to the fact that |V1+V2|^2 can be greater than |V1|^2 + |V2|^2. I.E. If V1 = 5 and V2 = 3, then VT = 8. VT^2 = 64, which is greater than 5^2 + 3^2 = 34.

Cecil, its not that |V1+V2| > |V1| + |V2|, its that |V1+V2|^2 can be > |V1|^2 + |V2|^2. There is nothing wrong with this vector math.

And I promise that this will be the last post from me on this subject.

Source record: 131968

I was wondering why capacitive end loading is more efficient than
loading with coils?
Is it due to the coils wasting energy due to resistance to changes of
voltage/current within the coils?
Is that where the losses occur?

Amazing the things that keep you up at night. 8-)

> Since you didn't tell us the frequency, nobody will be able to answer
> your question. If it is 1/2WL in the air, it will perform pretty well.
> If it is 0.04WL in the air, it will perform rather poorly.
=======================================

And if they are buried radials, and only 4 of them, it could be a very sick antenna.

On the other hand, even if the questioner had disclosed the all-important (to Guus) frequency, he would not have been answered with info of any greater accuracy or usefulness to him or to anybody else.

I don't like Accuracy. Uncertainy is often a better word. At least Uncertainties accumulate but Accuracies does not.

The questioner did ask about 1 foot above salt water. He didn't say what the salinity was. But the Guru's all know what salinity he has in mind in the same way as they have a sufficiently accurate idea what the frequency is in the first part of the question. (space left here for nit-pickers).

So for Jeffdeham's benefit, without any great personal experience in the matter, I would hazard a guess that an antenna above sea or oceanic water, at any height, has a radiating efficiency of 95 percent (almost perfect). The effect of height above water would be to change the radiation pattern of a vertical (which most people think they know but don't) in the vertical direction. And this to most people, I imagine, wouldn't matter very much unless they intended to use highly directional beams.

Take a look at program TOPHAT2 available in a few seconds from website
below.

The answer to your question is that loading coils have loss (HF loss
resistance and proximity-effect of the wire) and loading capacitors do not.
Makes sense ?

Martin,

appreciated to read your posting. Thank you. Sounds ok for me.
Since the idea is to setup the AP-10A on the roof (instead of a
long vertical, which i'm not asked to do), it will be a good
solution, besides Buddiople.

1933. Re: Why is capacitive end loading more efficient than coils?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-05 01:00:57 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <use62blhjr6hd5@corp.supernews.com>
Source record: 131872

There are a couple of reasons. One is that with inductive loading, relatively heavy current flows through a single conductor. In a top hat, the current is divided among several wires. Consequently, the conductor loss is lower in the loading component itself.

When an antenna is ground mounted, top loading also reduces the loss in another, and usually more significant, way. Top loading modifies the current distribution on the antenna, making it more uniform along the wire than it is with inductive loading. (It's more "spread out" along the wire instead of being large at the base and small at the top.) So for a given applied power or radiated field, you have less current at the feed point. The ground system current equals the feed point current, so top loading results in less ground loss. In terms of radiation resistance, top loading increases the radiation resistance, which is just another manifestation of the same effect.

|But watch out, it might create a black hole. After all, that
|excess 14.35 watts above needs another universe to flow into,
|hopefully the same one it flowed out of.

Actually, the circuit I was thinking of when I wrote the prior message
uses Impatt diodes to provide the negative resistance.

I am very familiar with the transmitter in the AIM-54C Phoenix missile
which uses a five-port circulator and three stages of Impatt
"amplification."

In this case, the Impatt stages were actually pulsed oscillators that
injection locked to the input signal and therefore appeared for all
intents to be amplifiers.

In operation, a phase-locked Gunn oscillator drives port one. Port
two has a single-diode Impatt stage that drives port three. Port
three has a three-diode Impatt stage that drives port four. Port four
has a 16-diode Impatt stage that drives port five. To make it even
more fun, all of these had pulsed current sources.

Trust me that in the early 1980's matching 16 Impatts to operate
together in the proper mode was really pushing the state of the art.

I've also measured a quite a few microwave transistor S-parameters
where |S11| was greater than one. More reflected than was input.

I meant reasonable feedpoint as in 'reasonably-low impedance'. Sorry. And, to save bandwidth, I'll admit now that there is nothing inherently 'unreasonable' with a Hi-Z feedpoint provided that you take it into account and somehow match it to your rig.

> The fact that they don't even specify the alleged
> patents tells you something.

I was poking around the patent office website (www.uspto.gov) and I couldn't find anything that resembled it. Of course, one can never prove a negative. Maybe the patent (s?) has nothing to do with the basic concept.

> between V1 and V2.

Steve, I just sent you an email that will correct your voodoo math concepts.

2 Sqrt(P1) Sqrt(P2) is ***NOT*** contained in P1 and P2!!!

Please read that sentence until it soaks in.

Pfwd1 is the forward power flowing into a Z0-match point from the left. The
Z0-match point has a reflection coefficient of Rho.

Pref2 is the reflected power from the load flowing back into the Z0-match
point from the right.

Your P1 equals Pfwd1(1-Rho^2) The rest of Pfwd1 is Pfwd1(Rho^2)

Your P2 equals Pref2(Rho^2) The rest of Pref2 is Pref2(1-Rho^2)

Your 2 Sqrt(P1) Sqrt(P2) comes from and equals the rest of Pfwd1 plus the
rest of Pref2 exactly as the principle of conservation of energy requires.

2 Sqrt(P1) Sqrt(P2) is really Pfwd1(Rho^2) + Pref2(1-Rho^2) which is the energy
involved in the wave interference. At a Z0-match, these two values are equal
so we can write them as 2 Sqrt(Pfwd1(Rho^2)) Sqrt(Pref2(1-Rho^2))

By rearranging terms, it's easy to see that expression involving wave
interference energy equals

2 Sqrt(Pfwd1(1-Rho^2) Sqrt(Pref2(Rho^2) = 2 Sqrt(P1) Sqrt(P2)

Your equation is correct but your error is in coming to the conclusion that
2 Sqrt(P1) Sqrt(P2) is contained in P1 and P2. The above derivation proves
that 2 Sqrt(P1) Sqrt(P2) is NOT contained in P1 and P2. It is only a
mathematical curiosity that the equation can be written that way. You
have been fooled by your own equation. You need to rewrite Part 3 of your
QEX articles and correct those gross errors involving voodoo vector math
and violation of the conservation of energy principle.

The 'Q' of a coil or cap is X/R. The 'Q' of a good capacitor is
usually much higher than the 'Q' of a good coil, therefore the
cap has less loss than the coil for the same reactance.

You'll need easy access to the roof. Every time you change bands with the
ap-10a, you have to adjust the length of the counterpoise wire to keep the swr
down. You'll also need to change the tap on the loading coil.

1942. Re: Extracting Reflected Power

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-05 02:52:18 UTC
From: gcd <gcdNOSPAM@austarmetro.com.au>
Message-ID: <3dc7325d@news.comindico.com.au>
Source record: 131881

Hi All,
sorry, no banana there.

lets ignore the 1/2 wavelength issue as it changes the steady state levels. Lets terminate the 150 ohm line with 150 ohm and lets assume it's lossless line.

So lets look at the 100Watt. A TX of 100W will do so into a matched conjugate load. Lets assume that the TX has an impedance of 50+j0 ohms. ie purely resistive.

So this tx can generate 100W into a load of 50 Ohm. This then equates to a source of 141.4Vrms open circuit and a source impedance off 50 +j0.

So with a 150 ohm TX line then the reflection coeff is (ZL-Zo)/(ZL+Zo) = (150-50)/(150+50) = 1/2. Just for the sake of it the VSWR would then be (1+1/2)/(1-1/2) = 3. and the TX power should be 1-(1/2)^2 = 75%.

The refelected voltage is incident voltage * reflection coeff = 141.4/2 * 1/2 =35.35V

Thus the forward travelling voltage is incident voltage + reflected voltage = 70.71 + 35.35 =106.06V.

Now lets look at power. As the 150 Ohm line is terminated the forward power is transferred and not reflected. Thus the power in the 150 ohm load is.

106.06^2 /150 = 75W just as expected

The other 25W was reflected at the junction of the 50 and 150 ohm lines and absorbed by the source impedance.

By placing a 50 Ohm load instead of 150, then there is another reflection coefficient to be determined. Probably easiest to use a smith chart based on 150 ohm and transpose the load 1/2 wavelength and then redo the above calcs on the load presented.

As far as extracting that 25W from the line then as proposed by others use a circulator isolator. The 100W is output by the TX into port 1 of a 3 port device. the 150ohm TX line is on port 2 and 75W is transmitted through, the other 25W is passed to port 3 where you would normally have a load to absorb it.

Hope this helps
Greg

>. . .

Careful here.

Consider a Thevenin source of 100 volts RMS in series with 50 ohms
driving a half wavelength open circuited 50 ohm line. The forward power
is 100 watts. The reverse power is 100 watts. The line is correctly
terminated at the source. Yet the dissipation in the source resistance
is zero -- none of the reverse power is absorbed by the source impedance.

What's different about your source that it absorbs the reverse power,
yet in my example it doesn't? Can you write an equation that shows how
much of the reverse power will or won't be absorbed by the source, that
will give the correct answer for both your example and mine?

ehsjr wrote:
"Tell her a yagi focuses "radio waves" similar to a lens that focuses light."

Yes. One could say a 3-element yagi has a director and a reflector in addition to a receiving element, the sole element connected to the radio. The director is in the desired signal path and concentrates energy on the middle receiving element. The reflector is in the opposite direction and turns around some of the energy which sweeps past the middle receiving element. Actually, it turns around much of the energy which would just pass the receiving element by and concentrates some of that energy on the receiving element. So the yagi benefits from energy picked up by all three elements if it is designed right, and it delivers much more energy to the radio than a single receiving element would.

HI All,

Being fairly new to HF vertical antennas I really didn't know what to expect. Due to space limitations, I am unable to install a ground radial system. According to the 4BTV manual, satisfactory results can still be obtained without the radial system.

Here's the trouble...SWR is very low on 10M,15M, and 40M. However, on 20M the SWR is 1:1 at the bottom of the band and climbs to 2:1 at 14.166Mhz. At 14.350Mhz, the SWR is off the chart.

Any suggestions?

TIA,

Dan

Shield to pin 1 is fine.....

The cellphone antenna ISN'T a 50 ohm port. If you disassemble an old
phone, you'll see the antenna port is actually a little "coil", a
helical loading coil that couples from the high impedance point on the
open end of the helix to the high impedance of the end-fed whip. So,
there is no way to connect a coax. The pin hole for the helix coil is
the RF output and is probably about the right impedance, but not
necessarily. Lots of tuning is done to try to make the crappy
cellphone antennas actually radiate "something" to the cells.

On the 2.4 Ghz WiFi band, we're having great success building beam antennas out of Pringle's Chip cans. See:
http://www.turnpoint.net/wireless/has.html
http://www.d128.com/wireless/
http://www.oreillynet.com/cs/weblog/view/wlg/448

If you look up inside the Pringles can on:
http://www.oreillynet.com/~rob/pringles/element.jpg
you'll see your 2.4 Ghz antenna. The distance to the "reflector", the can bottom is critical, by the way. The measurements are at the webpage.

Of course, in WiFi, we're interested in BEAM antennas to the local hotspot, in Egypt's case a broadband cafe.....

As far as phone range is concerned, at this high frequency, your best bet is to put a remote antenna fed with coax out of your mind and put the base unit as high up as you can get it. I know where there is one inside an inverted plastic pail 50' up a tower fed with AC power and a telephone line that works VERY well. The pail keeps the rain out and is transparent to the RF. A second "base unit" not hooked up to anything and only used as a handset charger let's the phone's batteries charged...er, ah, without climbing the tower to put the handset in the pail...(c; Range is about a mile or so....depending on how many OTHER people have similar phones on the frequencies. This one is in the country in the middle of a farm. The 2.4 Ghz phone works in the cab of the tractors anywhere on the large property this way....(c; To call the tractor from the house, simply dial the callback number and hang up briefly to make the phone in the tractor ring. Then both parties pick up, party line style, and are simply hooked to a null circuit providing DC to power the phonelines by the phone company...it's a test number. Works great from 50' up!
>
>The background for my project:
>A bunch of my buddies and I go camping in rural Southwest Indiana at a
>friend's "weekend property". Nobody can get cell reception there, but
>2 miles down the road everything is fine. So, I bought me an antenna
>book and have constructed a small ground-plane antenna for 800 MHz
>(Verizon) use, and I am going to stick in a big-old tree out there in
>the woods to see if we can get reception (when we want it).

AS this is more or less a fixed location, why don't we get a BEAM antenna to put up the tree and point MORE power to the cell site while increasing the listening gain, too!

Look at the beams on:
http://cellantenna.com/Antennas/yagi.htm
I'm very successfully using 10 element Decibel Product point-to-point paging yagis from remote beach houses on remote islands to point the

power from 3W analog bagphones running off a 12V power supply back to Charleston about 30 miles....while rejecting the connection attempts from an interfering roaming system in Savannah, GA. Set the bagphone on HOME ONLY and it locks onto Charleston, perfectly, even in heavy rain attenuation. These phones have been running for years like this....providing LOCAL telephone service back into city phones from an area covered by a bogus little POTS company where EVERYplace is long distance....and expensive.

A beam antenna up that tree, fed with 25-30' of a good quality RG-58/U coax with some nice mini-UHF connectors will work fine.....IF the phone has an RF connector on it....

>
> Thanks for any input!
>
> Jeff

You don't say the frequency. The efficiency could be anywhere from
good to horrible. When you deal with elevated verticals, and radials,
you should really think in terms of wavelength above ground rather
than feet. To equal the efficiency of appx 120 radials on a ground
mount, you need to be 1/2 wave up to do it with 4 radials. At 1/4 wave
up, you need 8-10. At 1/8 wave up, 50-60.
So you can see if your antenna is for 2m, it's pretty efficient. If
it's for 160m, it's not. Barely better than having 4 radials laying on
the ground.

> 73 de TF3KX, Kristinn

I wouldn't worry about it too much. If the pattern varies, their isn't
a heck of a lot you can do about it, and it likely won't hurt you much
anyway in the real world. The tuner in the rig just tunes what it sees
at the transmitter end. The same ratio of power per antenna element
will still occur no matter what the tuner does at the rig end. All the
tuner will do is increase the overall power leaving the rig, if the
rig reduced power due to high SWR. The power will go to the elements
with the closest match to 50 ohms. It will pretty much ignore elements
with an overly high or low impedance. So if you did 100 watts out with
no tuner, and 75% went to the 1/2 wave dipole, and the other 25% went
to other longer legs, if you used the tuner and jumped up to 200w
output, you would just double the numbers for each leg. The ratio will
still be the same. You would need to adjust the antenna legs
themselves to change the impedances, and thus change the ratios of
power that is divided between the elements. I'm think I'm correct on
this anyway...I'm sure someone will let me know if I'm not. If you are
running 50 ohm coax, and have a tuned 1/2 wave dipole, it will radiate
most of the power regardless of other legs unless one of the longer
dipoles just happens to be resonant also as a 3/4 wave, or whatever.
If that were the case, I would just try it and see how it works. I

don't really think it would be much of a problem. It's still going to be an efficient radiator overall. MK

Source record: 131892

Hi Roy et al,

In your example, the open cct is transposed back lamda/2 so (leaving the smith chart behind) the ZL provided to the source is ZL=-j*Zo *cotangent (2*pi/lambda *d) where Zo is the characteristic impedance of the line, d is the length in lambda. So here ZL = infinite.

Thus in this ideal situation, there is no power delivered by the source at all. Thus no dissipation in load nor source. However I see where you are going in the original example (i think)

Also note , transistors act more like norton sources, so if you have no load on your tx, the transitor dissipates all the power - so don't try this at home :)

ok, lets go that next step. If we look at the 150 Ohm tx line with the 50 ohm load, then using the smith chart we see that the impedance looking into that 150 ohm line is 50 ohm.

The thevenin source now generates 200W with 100 to the load and 100W dissipated internally as opposed to the 1st post i made where the source generates 100W with 75 into the 150 ohm load and 25W disspipated internally. (this what you were getting at Roy?)

However this is a steady state situation, for example, if this 150 ohm line were 10 millisecond long (yes a VERY long piece of lossless coax), then the mismatch at the source exists for 20 millisecond until the reflected voltages appear and then matching occurs, as it is the presence of the forward and reflected voltages & currents that present steady state. ie superposition.

So his proposal is - that for there to be 100W in the 50 ohm load then there is 133W in the 150 ohm line. ie 100W / reflection coeff = 133.33 (i think thats the idea being proposed)

There are voltages on the 150 Ohm line which represent a 133W into a 150 ohm load if you ignore phase. as has been indicated in other responses, vector addition is important.

If the load were switched at some point to 150 ohm then you have disturbed the steady state situation, now the 50 source is presented with 150 ohm load and the incident power is as above, ie 75W.(steady state)

You need to work with the voltages and current where the phase information is preserved. Thus the -1/2 reflection coefficient becomes important. You can do this manually, noting the reflections at each boundary until steady state is achieved. or use spice to do a transient simulation and you'll the

effects.

So if you turn on the tx for say 7.5 millisecond then you only get 75W into the 150 ohm line and if you switched over to a 150 ohm load you would only get 75W.

(my brain hurts - i'm too long out of university to think this hard)
Cheers
Greg

Greg wrote:
"Also note, transistors act more like norton sources, so if you have no load on your tx, the transistor dissipates all the power---."

Connect a collector meter to observe d-c current taken versus the r-f load on the transmitter. A linear amplifier is probably "Class-B". Current at no load is only enough to avoid "crossover distortion", just a few milliamperes. As r-f loading increases, so does the current taken by the amplifier.

The amplifier is not a device which gets all the current not taken by a load.

If there is no load on a transmitter, it delivers no power.

Greg also wrote:
"The thevenin source now generates 200W with 100 to the load and 100W dissipated internally---."

No. Most of the internal resistance of the r-f source is lossless resistance and derived from the switched-off time of the transistors. A transmitter matched to its load has an efficiency greater than 50% in many cases.

Greg also wrote:
"You need to work with the voltage and current where the phase information is preserved."

Not for the steady-state. There are only forward and reverse directions of power to contend with. The transmission line is a resistance (Zo). The power delivered to the load is the same power delivered by the r-f source when line loss is negligible. That power is simply the forward power minus the reverse power, both scalars.

Best regards, Richard Harrison, KB5WZI

**
yes it delivers no power as there is no load, but it dissipates power all
the same.

NO LOAD, or no DRIVE you be the judge - I read your comment here to say if I
have a TX pumping out 100W into 50 Ohm and I remove the load, the output
stage current drops to quiescent and doesnt generate power?

do we really want to get into the physics and hybrid pi models?

in a REAL transmitter there is a matching network that matches the output
impedance of a few ohms to 50 or 75 or 300 etc etc.

if we look at the hybrid pi model output section it consists of a current
source with the output impedance across it, hence the "LIKE a norton
source". If there is drive in the base it generates beta*Iin at the
collector irrespective of the load (lets stick to simple models)

so with no load, beta*Iin must flow through the norton source impedance, it
cant share it with the load as its not there, thus more power dissipation in
the device hence - hmm i smell silicon cooking.

Yes its more complex than that, ie in the above, a short circuit means no
dissipation in the source as its norton, but we know that dont happen in the
real world.

there are s paramters to consider, coupling between input and output, the
output cannot generate infinite volts into an open circuit like a current

source, and there are emitter resitances, collector resistances etc etc
.there are real world limitiations

**
sorry - you lost me there, internal resistance AND lossless??

This comment was made against a thevenin source, (an ideal voltage source of
0 ohm internal source impedance) with a 50 ohm resistance as the source
impedance. Yes, if a resonant ideal L & C were used then an impdeance with
no resistance could be made (parallel resonance) or infinte resisitance
(series) but this would be at 1 frequency but hey were talking ideals here
so thats ok.

In this example the thevenin source was 141.4V rms. The power delivered is
proportional to the load supplied. The "internally" referred to the 50 ohm
resistance which was the source impedance. Perhaps i should have stated that
in my mind the internal source impedance was resistive only.

**
thats the point, scalars loose all phase information, and phase is important
even in steady state, thats how you got to steady state in the first place,
with the incident and reflected voltage and currents which have phase
information.

and hence we get back to the original question. there is 100w into the 50
ohm load, yet it is on a 150 ohm transmission line, do you then agree withth
eoriginal proposal that there is 133w incident out of the 150 ohm line and
so must be 33w reflected back from the 50 ohm load?

sorry its late here and i've been a little obtuse.
Greg

I haven't been following closely. Who the heck is disagreeing with that?
Rho is 0.5. The load accepts Pfwd(1-Rho^2) = 133.33w(.75) = 100w. The
reflected power is Pfwd(Rho^2) = 133.33w(.25) = 33.33w

Dan,

Generally, what you would want to do is to move the 20 m trap down (closer to the feedline) to raise the 20 m resonance. You would then extend the top a little to compensate for 40m.

Very good Cecil in sticking to the point as to what "gain" is i.e. a
ratio.
The piece of wood that I was comparing it to contained some magic but
I was still able to claim a high RATIO. Nothing wrong with that
statement in this world. Andy Rooney regularly points to products that
point to "more" on its packaging.

Hello!

From my experience, I can tell that the doubl bazooka is a fine antenna for the home brouwer, with a good bandwidth/losses ratio as written in ARRL's Antenna Handbook.
This wide band antenna is also usable on the 3rd harmonic, I use one on 10 meter (not very useful on 86 MHz) and one for 144/432 MHz mostly during hollidays or portable operations as secondary antennas.
For the low HF bands, attaching the antenna to a non metallic supporting wire is mandatory!

Hoorah for Chip.
Perhaps you can tell me why one of the terms 'weight','length' or
'time' was not introduced by antenna engineers. Science has always
done this since man first came about on this earth, so why did the
antenna scientists follow the norm?
Can we expect in the near future that we will be buying produce
relative to its
weight in space or on the moon surface now that we accept the
reference to a dipole in space?

1964. How to directly connect frequency counter?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-05 14:56:18 UTC
From: cprstn54zz@att.net
Message-ID: <3dc7d7a3.441877046@news-server.optonline.net>
Source record: 131902

I just bought a Radio Shack #22-306 frequency counter (on clearance at $39.99). I know it works because it reports the proper figures for my handi talkies.

I had hoped that its antenna would pick up stray radiation when I TX from my FT990. Even though my field stregth meter is showing measurable RF in the shack, the counter won't register, even with the antenna against the coax feedline.

The counter also has has a 50 ohm BNC jack for direct connect. RS says not to exceed 1.4 V peak-to-peak on the jack.

Using Ohm's law, this seems to translate into 1/2 watt.

I had hoped to use this as the frequency meter for my 5 watt QRP XCVR. Unless I have someone stand under the dipole with the counter, it looks like this won't work using the counter's antenna.

Can I "T" off the radio's SO-239, with one leg to the antenna and one to the frequency counter? How do I lower the voltage to the counter to under 1.4 volts without sucking power? Can I just put a 500 ohm resistor in the center condutor of the leg going to the counter or do I have to maintain 50 ohms to avoid massive reflection?

C'mon Art.

You've deliberately evaded the question. Everyone here are not the
rubes you take them to be. We all known what a RATIO is and what a dB
is and that you have again failed to distinguish what is asked in the
simple question:
>> Roy, Art didn't say 10 "dBd". I think we can safely assume it is 10 dBi
As you have neither confirmed nor denied, instead simply wandering the
landscape like the ghost of Macbeth:
"to be or not 10 dB, what was the question?"

Anyway, thanks for the comedy,

73's

I`ve read few posts in this thread and accept Greg`s characterization of the original proposal.

There is a reflection coefficient (rho):
rho = R-Zo / R+Zo = -0.5

And, from SWR = Zo / R = 3

And from Pref = Pfwd (rho squared)

And from my Bird Electronic Corporation VSWR Slide Rule, the incident power is 133 watts. 100 watts is taken by the 50-ohm load, and 33 watts is reflected.

The return loss is 6 dB and the match efficiency is 75%.

Best regards, Richard Harrison, KB5WZI

Yes, introducing phasing even without the addition or use of lumped constants
can produce a situation where one would say 'gain of a dipole over a dipole'.
I presume the ARRL has a plan to stop the use of such a demoralising term.

|obtained without the radial system.

I owned one of these years ago but I don't remember what the manual
said about the ground system. I do know however, that the antenna is
supposed to be an electrical quarter-wave on each band, so the ground
system is extremely important.

You should have the antenna ground-mounted and have at least some kind
of ground rod at the base. This would be a very poor arrangement
without radials but if it's the best you can do than so be it.
|
| Here's the trouble...SWR is very low on 10M,15M, and 40M. However, on
|20M the SWR is 1:1 at the bottom of the band and climbs to 2:1 at 14.166Mhz.
|At 14.350Mhz, the SWR is off the chart.

The band that should exhibit the narrowest SWR bandwidth is 40 meters
since all of the traps are in play and the physical height is very
short for that band. The high ground and trap losses should actually
work to improve the matched bandwidth; i.e. the antenna is approaching
dummy load status. For the 20 meter performance you observe to take
place there has to be another higher Q resonance someplace.
|
| Any suggestions?

Yes, I'm guessing that the transmission line is part of the antenna.
Try putting another 10' or so or coax in the system and see what
happens to the 20 meter SWR. When it changes, report back.

Wes

Jeff,
It would help you to get hold of an article by 'Doty ?' that was
printed in the Ham Radio magazine many,many years ago, where the
question of buried radials was dealt with in depth (no pun intended)
and also compared to elevated radials.
Perhaps someone can point you to the actual title and year.

Cecil aren't reflective waves part of your antenna SYSTEM where
because of a
phase change these waves are radiated by the ANTENNA part of your
system.
I do not believe when you turn off your transmitter you are able to
pick up these reflected waves and weigh them.

mathematically defined quantity which is unitless." wrote:
"Hoorah for Chip."

Chip is exactly correct. Incidentally, it would be madness to try to evaluate antennas in general in any environment other than in free space unless we were specifying the combination of the antenna and its ground reflection.

As for unitless antenna gain, Terman says:
"Directive gain depends on the distribution in space of radiated power. The power input to the antenna, the antenna losses, or the power consumed in a terminating resistance have nothing to do with directive gain. Such factors are taken into account in terms of power gain of the antenna which is defined as the ratio of the power input to the comparison antenna required to develop a particular field strength in the direction of maximum radiation to the power input that must be delivered to the directional antenna to obtain the same field strength in the same direction."

One power ratioed to another power is dimensionless. As they say, the units cancel.

Best regards, Richard Harrison, KB5WZI

Art Unwin, KB9MZ quoted Cecil who wrote:
"When I was working at Intel, we had some connections to the Far East that were so bad the reflections made communications virtually impossible."

When I worked at Tenneco, my conversations with Australia seemed to be made through multiple satellite hops. Despite echo cancellers, the long delays made the conversations virtually half-duplex and annoying.

Art also wrote: "I do not believe when you turn off your transmitter you are able to pick up those reflected waves and weigh them."

Maybe not. But, the waves keep traveling after the transmitter is turned-off until the waves on the transmission line have been radiated or otherwise disposed. Of course they travel on in space for much longer. We see light from events occurring far out in space aeons ago.

Best regards, Richard Harrison, KB5WZI

Ken,

Sounds like a good solution. I would like to point out that 1.4 V peak-to-peak into 50 Ohms is about 5 mW not 1/2 Watt. That translates to +7 dBm. If you apply 1/2 Watt to the counter, you might blow the front end or prescaler.

What do u guys this of a A 99 cb radio antenna with ground plane kit.
I need some specs on the A 99 like how db gain do u get and any other
good info I
might need to know. I going to use this antenna with a old cobra
89xlr and
how many mile range will I get if the antenna is like 30ft high.

> Is is it comparable to being 1 foot over salt water?

Whoops, the frequency is 7mhz.

From what I have read is that even being .1 wavelengths above the
ground makes
for the vertical being way more efficient and 4 radials can be the
same as having
60 plus radials (just a guess on the amount of radials).
Hence the question is that the same as being over salt water
conductivity wise?
Or another way of putting does ground have a real effect on a 1/4
vertical with let's say
120 radials?

Thanks!

Jeff

During steady-state conditions, all the generated power (minus T-line losses) reaches the antenna. That power is riding on the back of the previously established standing waves (assuming standing waves have a back to ride on. :-)

> I do not believe when you turn off your transmitter you are able to
> pick up these reflected waves and weigh them.

Theoretically, we should be able to measure the power into a load after the transmitter is disconnected. We would need a clean disconnect to trigger our scope/analyzer and I'll bet we will see all sorts of transient voltage across the load after the disconnect. Voltage across a resistive load equals extracted power even during transient conditions.

But if you want an example that makes everything clear, consider a lossless transmission line system that is one second long. Given a forward power of 133.33 joules/sec and 33.33 joules/sec reflected, a one second long transmission line would contain 166.66 joules of energy, 133.33 joules of forward energy, and 33.33 joules of reflected energy. You can certainly burn your fingers with 166.66 joules.

I had a 40m 1/4WL vertical with 8 radials at 20 ft. It was a dog
compared to my dipole at 40 ft. It wasn't even worth leaving in
the air as a lightning rod.

Thanks for the comments Bill. The Eagle DX will be used primarily for a "go-to" antenna and/or a second radio antenna for contests. Not really used as the primary station antenna. Cannot pass up the price and I already have the mount in the yard.

As far as the coax was concerned. The coax was the one that came out of the antenna. Not the RG8X coming from the shack. The antenna was only about 4 weeks old and the coax connector was sealed. Somehow water got in the coax.

Thanks again!!

Touche`!

33,000 ft lbs/ min, 746 watts and one horsepower may be equivalents, but their units are different.

In the case of watts per square meter produced by two differing antennas under the same circumstances, the units in their ratio fall out leaving only a numerical ratio. A power gain, not decibels, but easily converted to decibels if that is your pleasure.

I had a comeuppance coming after my tasteless maroon cap story.

Ryan...for shame!
Here you have an article titled, "A Verbal Graphic Description of Gain Antenna Operation". It was in CQ magazine back in the late 70s. The author is local. Most in the club should remember...well, then again, many of them are getting along in years. I've seen it happening over many decades....Now we were talking about what?

Basically in a Yagi:

The element lengths and spacings are such that, going step wise.

1. The signal is radiated by the driven element
2. The radiated signal creates a current in the reflector whos length and spacing is shuch that when the reflector reradiates the signal it will be out of phase with the next cycle from the driven element which cancels much of the signal to the rear.
3. The director, like the reflector reradiates a signal, but it's spacing from the driven element and length put it's signal in phase with the next cycle from the driven element, adding to the signal strength in that direction.

Element lengths and spacings are often varied a bit to give wider band width, at the expense of gain. Higher front-to-back also comes at the expense of gain. That being the case, most Yagi antennas are a compromise between maximum gain, front-to-back, and bandwidth.
The article takes you through it step-by-stp.

If he can find the article, I'm certain the author would be happy to make some copies for you. As CQ holds the copyright, others would have to contact them to get the complete article.

Don't let WA8ULX spoil your day. I have tuned and used one on 10 meters
for the past 15 years and it works quite well.

It's really not possible to answer your questions with any degree of precision without knowing the type of terrain you're near, what obstructions (buildings, trees, hills, etc.) are nearby, and so forth. With my experiments, I determined that the Antron was the best vertical I had used and I made on the air tests with several other verticals and switched back and forth. The Antron equalled or surpassed (slightly) a 3/4 wave vertical and was 1-2 S units higher than 1/4 and 5/8 wave verticals . Measurements were made at a range of less than 20 miles. Most people using a "copy stick" would disagree with the findings but I have confidence in my findings for the conditions under which the data were collected.

As a side note, the radials improved the signal, further out, but only a fraction of an S unit, not worth the cost in my opinion.

Best of luck...

Dan,

Sounds like the antenna needs to be adjusted to get the SWR down for the parts of the band that you want to use.

Unfortunately, some brands seem to want to defy the laws of physics and state radials are not needed. This is NOT true. For those that believe, no proof is necessary, for those that don't believe, no proof is possible. A ground mounted vertical without radials will perform but not nearly as well as one with radials.

73s,

Evan

Radio Works has the smaller plastic egg insulators. Texas Towers has the large insulators for towers or big masts. Both have web sites.

> same as having
> 60 plus radials (just a guess on the amount of radials).

Four radials at .1 wave are more efficient than the same four on the
ground, but you still have a fairly lossy system overall unless you
are over very good ground. For four radials to equal 60 ground mount
radials, they need to be appx 1/4 wave up. I'd have to more closely
calculate, but just guessing, I'd say you would need 40-50 radials at
.1 wave up to equal 60 ground mounted. According to graphs I have in
books, at 1/8 wave up, you need appx 60 to equal 120 on the ground.

> Hence the question is that the same as being over salt water
> conductivity wise?

I would think being over salt water with a low GP would be better than
120 radials on "average" ground.

> Or another way of putting does ground have a real effect on a 1/4
> vertical with let's say
> 120 radials?

Well, to me it's sort of backwards from that. You would use that many
radials in order to not be as effected by the ground quality, or lack
of it. You have a more stable system, and you also know exactly what
you have at any given time. Or at least at a minimum anyway. But if
ground cdx improve, even a system with 120 radials would slightly
improve also I would think. You can use more than 120 radials. That
number can be improved upon for the extreme hard core of vertical
users. I doubt it's worth the trouble though.
Many times you don't need 120 radials if your ground quality is good
enough. The increase from 60 to 120 is small. Less than a db normally.
I know from experience, if you want to run a 1/4 wave vertical, and
want good solid results with only 4 radials, it has to be at least 1/4

wave up. Sure, you can run one at 1/8 wave with 4 radials and have mediocre to decent results, but don't plan on it being a dx buster like the higher one would be. The differences in ground losses are quite noticable between the two. I was able to test this easily being I used a telescoping mast as a support for the vertical. I ran it low a couple of times while I was working on things. It wasn't near as good as when it was up at 36 ft. "40m".
I also ran the same antenna ground mounted originally. I got up to 32 radials at one point. It wasn't even close to the antenna at 36 ft with 4 radials. That tells me that even for a place like Houston, which actually has fairly decent ground quality compared to many areas, using 60 to 120 radials on a ground mount is not a waste of time for top results. If it were, I wouldn't have seen the large difference.
The ground mount with 32 radials was never more than mediocre, and usually about equal to a dipole at 36 ft on 1000-1500 mile paths.

Older analog phones did have 50ohm ports.

My Technophone Mk2 (~1987) has [50/75 Ohm] SMA connectors. You could screw
on a quarter wave stub, a base loaded 5/8 wave antenna (gave +3dB allegedly)
or coax to an external antenna (here I used a dual semicoil design that gave
an alleged +4.5dB improvement, probably enough to make up for the losses in
the cable).

Some more recent phones do have push fit coax connectors of some kind or a
minature coax at one end of the plug.

Folks,

I need to tune my Alpha Delta DX-EE multiband trap/parallel
dipole.

My question is, there surely must be interaction between
the wires, so which bands do I tune first? 10 Meters
first and 40 meters last?

or the other way around...

10 meters is dedicated wire
15 meters is dedicated wire
20 and 40 are shared with traps (ok, Alpha Delta
calls them ISO-RES coils)

```
40 Meters 20 Meters 20 Meters 40 Meters
--------||||||----------------------------||||||---------
-----------/|\----------- 15 Meters
----/ | \---- 10Meters
|
|
```

Thanks,
George

Ryan...for shame!
Here you have an article titled, "A Verbal Graphic Description of Gain Antenna Operation". It was in CQ magazine back in the late 70s. The author is local. Most in the club should remember...well, then again, many of them are getting along in years. I've seen it happening over many decades....Now we were talking about what?

Basically in a Yagi:

The element lengths and spacings are such that, going step wise.

1. The signal is radiated by the driven element
2. The radiated signal creates a current in the reflector whos length and spacing is shuch that when the reflector reradiates the signal it will be out of phase with the next cycle from the driven element which cancels much of the signal to the rear.
3. The director, like the reflector reradiates a signal, but it's spacing from the driven element and length put it's signal in phase with the next cycle from the driven element, adding to the signal strength in that direction.

Element lengths and spacings are often varied a bit to give wider band width, at the expense of gain. Higher front-to-back also comes at the expense of gain. That being the case, most Yagi antennas are a compromise between maximum gain, front-to-back, and bandwidth.
The article takes you through it step-by-stp.

You can also get a couple people to help with paddles and a bath tub.
The one in the middle uses the paddle to create the radiator
The one behind is the reflector and the one in front the director.

1. Have the "radiator" start making waves.
2. Have the "director making waves in phase with the "radiator"

3. Have the "reflector" make waves that are out of phase with the radiator.

It works better in a pond or swimming pool using paddles made of a board about 3 feet long. A 3' long 1 X 4 on the end of a 2 X 4 for a handle works quite well.
You not only can see the antenna work, but you can even see the waves to the side come out and cancel, or add in spots.

However, unless the person is basically technically minded they really will have very little grasp of how an antenna works even with the demonstration.

It's like trying to explain how a computer works to the average person (actually the vast majority of the population) It adds because they pressed <2> then <+> and then <6> which gave them "8". They wouldn't get past the binary representation of "2", let alone trying to explain a register.

If he can find the article, I'm certain the author would be happy to make some copies for you. As CQ holds the copyright, others would have to contact them to get the complete article.

Help me out here Richard as I want to add 'length' so we
introduce something that does have units.
If we put 1 amp, say 1 Au, as the vertical side of the graph and then
horisontally we have 1/2 wavelength, couldn't we draw the sinosoidal
radiation curve on this graph so the AREA underneath the curve
does have units? I am not sure what the actual units would be.
If instead of rotation we have a linear uniform acceleration of electrons
so instead of a curve it would be a straight horizontal line providing
the maximum area possible (max radiation possible?) from a dipole.
(uniform accelaration I was thinking would be something like that of gravity)
Would something of this aproach help us to provide gain with units ?
From the above we can show that a dipole efficiency compared to a absolute max
but I am not sure how we can use this aproach to get to a point where gain
can have units. Just musing Richard to see how we can get back to realistic
figures without having to journey into 'space'. Roy, do you have any thoughts
in this area ?
Regards
Art

Make them! I have seen PVC pipe chunks as well as sheets of plexiglass
used for insulators, unless you want specifically the egg-type insulators.

This stuff can also be found at local construction sites, in their junk
piles, which should be really great for the extremely frugal ham. Just make
sure to ask the contractor!

You can plot, if you want, the current (in, say, amperes) along a wire vs the distance from one end (in, say, meters). Then the area under the curve is ampere-meters. However, this doesn't tell you what the radiation pattern or efficiency of the antenna is.

Remember, the current at each point has an associated phase angle. Although the current-length product (the area) along the wire tells you the field strength from that portion of wire, it doesn't tell you how it's adding to or subtracting from the others. The radiation pattern of the antenna is determined by the *vector* sum of each current-length product in each direction. If the wire has zero conductor loss and it's in free space, the efficiency is 100%, no matter how you bend the wire or what fancy curve of current vs length you end up with, or what total area lies under the curve. So there's no direct correlation between the area under the current-distance curve and the antenna's gain, pattern, or efficiency.

If you try to maximize the current-length product, you'll end up with W8JK type designs (close spaced elements driven out of phase), which have relatively high currents on the wires. But alas, there's no magic here. The fields produced by these currents largely cancel, so you end up with moderate gain -- providing you can maintain reasonable efficiency when faced with such heavy currents.

After any calculation is run by EZNEC, you'll see exactly the curve you describe in the View Antenna display. (Along each wire is an extra line whose distance from the wire is proportional to the magnitude of the current.) It's handy for seeing which parts of an antenna are contributing to the pattern and the relative magnitudes of the fields produced by various elements.

Hi CAM,
unfortunately I am, I was sort of hoping that was coming across from my posts :)

the problem with the premise that there is 133W in the 150 ohm line is that you make this conclusion looking only at the load end of the line, ie using the reflection coeff etc you are assuming that looking into that line is 150 ohm. Its not, at the other end is a 50 ohm source, not a 150 ohm source.

Cheers
Greg

I suspect they want a "drop in" type connector, instead of one that has to
be screwed in. I have a Larsen "Quick Mount" slide in mount for my dual
band transiever. It has a connector that's a BNC, modified so that it can
be slide in, without requiring a lock.

Never mind that we can measure 133.33w of forward power and 33.33w of reflected power on a wattmeter calibrated for 150 ohms?

The 50 to 150 ohm impedance discontinuity at the 50 ohm feedline to 150 ohm feedline junction has the same magnitude of reflection coefficient as the 150 ohm feedline to 50 ohm load junction. The 50 ohm virtual impedance match you see looking into the 150 ohm feedline is the *result* of interference patterns set up by reflections and re-reflections of the forward and reflected waves when they encounter the real-world impedance discontinuity at the 50/150 ohm junction between the two feedlines. The 50 ohm matched virtual impedance is the *result*, not the cause of anything. Virtual impedances, like this one, are the *result* of the math model we use that make thinking about the situation a little easier. What happens in reality at the impedance discontinuity can best be understood using the principle of superposition (and/or quantum physics).

Assume the following *general* case of a 50 -> 150 ohm junction of two feedlines. Note that this is a general case as opposed to the special matched case that we have previously been discussing.

```
Source-------50 ohm feedline----+======150 ohm feedline=======50 ohm load
Pfwd1---> Pfwd2--->
<---Pref1 <---Pref2
```

If Pref1/Pfwd1 is not equal to Pref2/Pfwd2, then wave interference exists. If Pref1/Pfwd1 is less than Pref2/Pfwd2, then there is destructive interference on the source side of the junction with a corresponding constructive interference on the load side of the junction. If Pref1/Pfwd1 is greater than Pref2/Pfwd2, then there is constructive interference on the source side of the junction with a corresponding destructive interference on the load side of the junction. If Pref1/Pfwd1 equals Pref2/Pfwd2, then there is no interference and the forward and reflected waves are orthogonal to each other at the impedance discontinuity.

The interference patterns cause the virtual impedances. The virtual impedances are the *result* of superposition and are not the cause of anything. Well, I must admit that virtual impedances do cause certain things - many firings of neurons in the human brain and much ado over nothing. :-)

I tried and tried but I never heard any signal, day or night, that was
stronger on the vertical than on the dipole. In addition, the noise level
on the vertical was two S-units above the dipole's. In my case, it was
a lot of work for absolutely no reward.

> and somehow match it to your rig.

OK, I understand now. But the result is still the same - if you have a
low-Z feedpoint, it's fairly easy to match it to 50 ohms with much
less loss than resistive loading. One's money is much better spent on
an SGC-type autotuner. For far less money, a simple L network will
match almost anything, and freeware like Reg Edwards' DIPOLE3 or
ENDFEED programs will give you L and C values in a few seconds. Or
adapt CAM's transmission line idea.

For the yacht example, compare the price of Maxxcomm to the price of
an SGC-type tuner of the same power level.

'zactly. The patent could be for the method of potting the thing in
epoxy, for all we know.

When they don't give a clear explanation of how it works, and/or refer
to patents without giving the number, you gotta be suspicious.

And here's the rub: Even an antenna with 4% efficiency will make some
contacts. Feed it 100 watts and it will radiate 4 of them, putting you
at the same ERP level as a QRPer running 4 watts out and an antenna
with 100% efficiency.

Just don't expect "100 watt" results.

Amidon has a balun kit for about ten bucks that can be wound in a 4:1
configuration. The part number is AB240-125.

> --
> cheers, CAM http://www.qsl.net/w5dxp

Our results on 40 are FAR different. We are, what, about 20 miles or so apart here in the South Central
Texas area? I don't spend the time working the CW DX contests on 40 like I used to. I've simply run out of
countries to chase in them! But here's the summation of over twenty uears of comparison to what you just
posted, from my perspective. We are talking about almost 50 years of experience at my end.

Early on I used a dipole at from 40 to 50 feet up on 40 CW. Over the years my country count in the either
the ARRL or CQ contests of perhaps 60-80 countries per test, conditions, skill and whatnot. I switched to a
quarter wave vertical at ten feet up with four radials over the same ground at the same location. End
results; a steady average of roughly 70-90 countries per contest. Down came the dipole forever.

I switched to a pair of three element wire low quads just for funzy, suspended between an experimental 80
meter 4 square. Results; some 80-90 countries in the annual bug smashing tests for DX. But I did break my
all-time total number of single-band 40 CW total contacts in the ARRL SS CW tests which had stood, at that
point since 1954 at about 700 - 40 meters only. Even corner fed, it seems like it was ionizing enough air
over the place above me to maybe help out. Whatever, it was a GREAT Stateside directional array! Huge
grin. It also produced my first ever clean sweep on 40 CW single band in the SS. Grin.

Frankly, the single elevated vertical on 40 CW produced about as good results in cracking the DX pileups as
the wire cage game!

Seeing the comparison between it and a single elevated vertical on 40, I went ahead and created the full 40
meter elevated 4 square, all shunt fed and totally grounded elements, by the way. The shunt

fed issue is the
way I first put up one of these elevated 40 meter verticals and it has seriously reduced the RF into the
shack area with the lightning strikes.

Poof ... up went the country total in the tests, reliably and repeatably, to about the 100 country total per
test. More important, in the tests, I began to consistently hear about ten more countries each test that I
could contact! Thus the practical effect of, "If you can't hear 'em, you can't work 'em", has come full
circle. And that's with a pair of lovingly hand crafted 4-400's and the legal limit and no more being used
to drive all of this stuff since 1974 and a pair of 4-65's since 1958 or so.

In other words, it will take better than an elevated 4 square with four radials to get through the pileups,
in practice, to work what it will hear now at this QTH.

The elevated 4 square on 40 CW has now been up since about 1985 out at the place. It's had a total of three
phase boxes replaced being blown to bits by lightning strikes, but with the solid grounded gamma matched
elements, and panel protection on shack entry for the lines feeding it, nothing has proceeded into the shack
from it. That does mean, for 'truth in lending' purposes to this gossip being lent, that there is ADDITIONAL
grounding effects here! Under the poles at the bottom of them where they tie to a ground stake each, that
ground stake does have several short feeler radials which are there to help sink the strike of Dr. Zeus; they
seem to. I'm sure that this contributes somehow, a tiny bit to something, but I've not got time to go
modeling all this tripe.

At an original 300 CW only confirmed 40 CW application for DXCC, over 45 years or so in the making, the point
of all this, in practice, has come clear. The now ten more for 310 confirmed on 40 CW only are emphasis for
the point. I can hear what I can't work, grin, as I am frequently winding up going out to the place and
coming back with this, "Oh rats and hampsters", feeling now! As you know, staying up all night to work this
^%$&^%$ on 40 or 80 takes its toll in other ways!

Now all this has another very important point in answer to the original poster's question. It all depends on
what kind of ground conditions you have under the array for 40 meters, at YOUR location!

Where we may differ in our results in practice, even though we are only a few miles apart here, may have to
do with soil conductivity. My site is in the appoach area to the Navasota River bottoms. If they ever get

around to building the Millican Reservoir they have politcally fought over for years, the water for that huge
pond will in the property just Southeast of me, and it's only a ten acre chunk. The lay of the land drops
off close to 100 feet into the flood plain for it right smart like, and there are 60-80 foot ravines in our
land alone that are co-incident to this issue of grounding!

This place does have pretty fair conductivity, compared to just a few miles away where, in Texas, we hit the
pine tree sand soil. The fault line which goes all the way from up near Texarkana down and over just this
side of Navasota, and over this side of Brenham into Austin and out into the Hill Country, is just on the
other side of the Navasota River we are talking about.

Those poor souls in the other side of the Navasota Trench who are hames, really do have worse soil and ground
conditions for antenna site considerations. And there will be no way either or us will EVER do what even a
dipole can do up in the Waco area, up in the Greenville area where Gerald has his awesome 3 element
full-sized rotary array on 80 meters! Part of your answer, and that of the gent who posted the question,
may lie in the actual ground conditions under this mystical vertical or dipole question.

Your case may be exactly what it is for that reason, propagation come to Jesus meeting time at the earphones!

OTOH, the only way I will ever be able to get a dipole here to be any better than a vertical on 40 CW, for 45
years worth of experience and proof in the logs at what can be heard and worked, is for there to be more than
one of them up there!

That will also mean at least two of them would have to be there at better than 60 feet to be as good as what
I've got. To get any better TRANSMIT gain so that they can hear me whom I can't work now, it will have to be
at least THREE of them at least at about 80 feet, per the charts, in a rotary array.

But there is good argument about another variation of that which I think would be even better for most us
hams.

Gerald and I, K5GW, have had some discussion about this. My theory is that the ideal 40 meter or 80 meter
antenna, for what we hams really seem to want, in practice, is a SIX element horizontal rotary array at 90
feet up on 80 or 45 feet or so on 40 meters. If you do the model work on that, you'll find that the
radiation pattern is awfully clean and the averate vertical takeoff angle really approachs

what the average
ham probably wants. That yet with enough energy in the lower angles to do what is needed, in practice, for
the really long haul stuff.

He says he will erect it and test it on 80 if I will build it, and compare it to his current 3 element
creature at 195 feet up.

Gerald is, as far as I have ever known over twenty years of knowing him, a man of his word.

Sort of like the song Marty Robbins had out years ago, "All drinking stopped and the tick of the clock, said
that Death would wait ten seconds more..."

****

I believe that this gent, and I too, would find that a single dipole up at 120 feet or so on 40 would
seriously be a better antenna than the elevated vertical at a quarter wave up on that band. That given
average ground characteristics under the two devices. But at 40 feet, no way, in practice, for at least the
DX chasing game, based on what I see here.

The results and signal of W8JI on low band, support my contention, I hold out to you. But they are not from
a 40 meter dipole at 40 feet up as far as DX and low angle paths are concerned, I hold. And they are from a
decent ground conductivity location as well, I think.

However my location is a very quiet low noise rural location, in an undisturbed soil situation, with at least
average to perhaps a bit better than average soil conductivity. Thus maybe that also anwers why my results
have been as they have been for some 45 years at this.

Well I defer to your judgement for the moment.As I said I am just
musing.

> Remember, the current at each point has an associated phase angle.
> Although the current-length product (the area) along the wire tells you
> the field strength from that portion of wire, it doesn't tell you how
> it's adding to or subtracting from the others.

I have a problem with that statement as an engineer.You are refering
to to radiation but only to that created in cyclic form only?

>The radiation pattern of
> the antenna is determined by the *vector* sum of each current-length
> product in each direction.

So for only considering a cyclic form of radiation you have meaningful
unitsring to radiation created in cyclic form i.e relative to
frequency ? This being equal distribution of energy either side of the
radiatorShould we not as engineers think in absolute terms ?
Are not the limits of distribution created when all radiation is
squeezed from one side to the other?

If the wire has zero conductor loss and it's
> in free space, the efficiency is 100%, no matter how you bend the wire
> or what fancy curve of current vs length you end up with, or what total
> area lies under the curve. So there's no direct correlation between the
> area under the current-distance curve and the antenna's gain, pattern,
> or efficiency.
I don't feel comfortable by deviating to space at this point.
So far I would suggest that in absolute terms we have established max
possible radiation which is that created in linear form. We have also
established max radiation of a standard dipole (Again looking at the
area under the curve) Thus we have a comparison of radiation compared
to the absolute. We also know that this radiation is balanced either
side of the radiator
If we move area from one side to the other by 'squeezing' have we
not generated gain on one side which is a measurement of area?
As for wire resistance electric engineers have handled this quite
easily in the past without venturing into outer space.
In re re-examining the above it is to be noted that Newton laws with

respect to acceleration (the underpinnings of radiation) also said
that every action has an equal and opposite reaction which says that
wee have to consider cycles
(area above and below the graph line) which provides equal are on both
sides
and we must also admit that deceleration must also provide radiation.
Unfortunately this puts me in the position of say radiation is a
series of pulses which I said some ten years ago on this antenna group
and was met with total opposition (That's what happens when you start
thinking beyond your qualifications)so what is needed bright and
educated people who are also uridite
and willing to look beyond difficulties for resolution and not those
who live for derrision. I cannot do this because I have personal
problems but I am confident that there are many of this group can
carry this aproach with eloquence. Yes Richard, it would be crazy not
to separate ground reflected gain
and I believe that the above aproach does just that. Since ground
reflection is not the creator of radiation it falls into to the
reflected or redirection of radiation as would a a multi element
array.
Best regards and apologies to those who feel such discussions are not
pertinent
to what is considered as just a hobby.

I am now at a position to finalise a new 'home brew' antenna
that may be of interest to some.
It is quite a long unsevered dipole,320 inches per side and to
which I have also added capacity hats (6 inches diameter)
To this dipole I have added a loop antenna
at its center where part of the loop and the capacitor
(variable upto 1000 pF/5kV) is enclosed within the dipole element
I will feed this dipole combination by a delta feed and probably
will have to add a transformer because of the antennas high impedance.
I cannot model this because of the partial loop radiation that
is shielded . Thus I am making the antenna to determine what
radiation pattern it provides at different frequencies obtained
thru variation of the capacitor.
Perhaps some would like to predict what I am about to find,
or even to model it if they have the capabilities. (tower ht
820 inches)

2038. Re: Tuning trap/parallel dipole question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-06 16:57:11 UTC
From: Tarmo Tammaru <t-tammaru@home.com>
Message-ID: <zrScnVzUCYUG1FSgXTWc3A@comcast.com>
Source record: 131727
Cross-posted to: alt.ham-radio.hf,rec.radio.amateur,rec.radio.amateur.antenna

George,

With parallel dipoles, the longest wire has more effect on the shortest. Whereas, with a trapped dipole, the higher frequency has to be adjusted first. Since the 20/40 is the longest wire, I would adjust:
20 first
40 second
15 next
10 last

After you have done that, you may have to repeat the whole think. I have multiple dipoles at 12, 17, and 40 meters (no traps). When I ran the thing on EZNEC, the only way I got it to converge was to go 40>17>12. This worked out in the real world. Your 20 m trap will probably prevent the 40 m from interfering with the 15.

Folks,

I need to tune my Alpha Delta DX-EE multiband trap/parallel
dipole.

My question is, there surely must be interaction between
the wires, so which bands do I tune first? 10 Meters
first and 40 meters last?

or the other way around...

10 meters is dedicated wire
15 meters is dedicated wire
20 and 40 are shared with traps (ok, Alpha Delta
calls them ISO-RES coils)

```
40 Meters 20 Meters 20 Meters 40 Meters
--------||||||-----------------------------||||||---------
-----------/|\----------- 15 Meters
----/ | \---- 10Meters
|
|
```

Thanks,
George

Art Unwin, KB9MZ wrote:
"If instead of rotation we have a linear uniform acceleration of electrons so instead of a curve it would be a straight horizontal line providing the maximum area possible (maximum radiation possible?) from a dipole."

Terman`s 1955 edition of "Electronic and Radio Engineering" knows all and tells all. Chapter 23 on antennas begins on page 864 which also lists most of the other antenna books you would need.

On page 866 is Fig. 23-2 showing radiation contributions of elemental segments of an antenna. They are proportional to the current in a particular element of the antenna. They are supportive in producing radiation as long as the currents aren`t at odds with each other. Figs. 23-3 and 23-4 on page 867 show what happens when an antenna exceeds 1/2-wavelength which causes phase reversal in some wire segments.

One can make an array of 1/2-wave elements, stringing them together for whatever length by including phase inverters every 1/2-wavelength.

Or one can make an array of 1/2-wavelength elements side by side in a plane, driving them all in the same phase, etc.

Art`s interest seems to be in a simple dipole used on more than one band, a method of matching that dipolte at its junction with its feedline, and application of that dipole to a parasitic array. I`ve tried to read between the lines of Art`s postings and may have it wrong.

From Art`s statement at the top, I gather he wants more current towards the ends of his dipole so they aren`t loafing in the radiation department.

For a single band, a short dipole with capacitive hats at its ends may give fairly uniform current distribution. See Terman`s Fig. 23-24 T-antenna with its earth image on page 887. A dipole in space works the same if the image is replaced with real wire.

For multiband dfipole operation, the capacitive hats could be combined with traps for coupling between segments. Yes, traps are lossy.

See Cecil`s multiband dipole matching scheme for something practical.

Best regards, Richard Harrison, KB5WZI

Sorry, I can't make much sense out of your response.

What's a "cyclic form" of radiation? Something new we can apply to make all our miracle antennas work, like "critical coupling" or "orgone"?

The radials are basically a decoupling section on that antenna. They
decouple the feedline so it doesn't act as part of the antenna.
Currents on the line can skew the pattern upwards off the horizon and
you lose any gain you might have over a 1/4 wave.
They don't make a "drastic" difference, but I think they are worth
using overall. BTW, I bet if you converted your 5/8 antenna to having
3/4 wave sloping wire radials, it will be the best of the bunch. I
also made the same tests a few years ago, but the 5/8 always won here.
But, I was working quite a bit farther than 20 miles at times.
Probably 30-40 miles or even farther many times. Also, the normal
skywave stuff ..Also, the 1/2 wave I used was a ringo with added
decoupling, not an A99. But the gains should have been appx equal for
both. Decoupling the 1/2 wave made a noticable difference here. But
here, the 1/2 wave even decoupled was always the 2nd best antenna. But
it was no slouch at all. But the 5/8 with 3/4 wave radials beat it by
a noticable amount every time here when working 30 miles away. I
always used 36 ft as the base height for all the antennas. "radio
shack pushup mast" Also, as a side note...Those A99 antennas are 1/2
wave radiators. They don't have any less or any more gain than any
other half wave radiator. The degree of decoupling can effect the
results though. Ignore any inflated gain numbers seen in ad's.
According to some I've seen, a 3 el yagi would be lucky to compete. Of
course, in the real world a 3 el yagi would outdo a A99 by a large
margin. You can check out a page I did on modeling the different
types. http://web.wt.net/~nm5k/acompari.htm
I came up with one model as what I think is the "ultimate" vertical
for 10m use. But it's more of a dual 5/8 antenna. Kind of a perverted
isopole for 10m except I would just use sloping radials instead of

cones. For the best results, it should have a 2nd decoupling section under the lower 5/8 section. You could use a line of coax and a 2nd set of 1/4 radials.
Actually, it would probably work fairly well with no extra decoupling at all. I used no extra decoupling on the 5/8's with 3/4 wave radials. The antenna with 3/4 wave radials is easy as the antenna requires no extra matching tweaks, and worked well. Modeling that radial length showed it to give you the "standard" gains expected from a 5/8 vertical. So it seems to cure the problem many complain about as far as too short of radials, and the higher angles caused by those. Which is true, when using 1/4 wave radials. MK

==========

Get a 2-inch (50mm) diameter, fat ferrite ring, preferably NOT
power-frequency quality.

Wind on 7 or 8 turns of 18 or 16 gauge Radio Shack twin speaker wire or
something similar.

Make a few soldered connections, and the job's done. To make sure of 160m
add another turn. But 10m might have a slightly different imedance ratio.
Not that it would matter very much. Don't suffer from delusions of accuracy.
Marconi never suffered from such problems.

For performance versus frequency, download in a few seconds, program BALUN4
from website below. Run immediately.

I need to tune my Alpha Delta DX-EE multiband trap/parallel
dipole.

My question is, there surely must be interaction between
the wires, so which bands do I tune first? 10 Meters
first and 40 meters last?

or the other way around...

==========

There is no answer to your questions. Every antenna system is a victim of its own environment, height, sloper or V, soil characteristics, adjacency to mast and buildings, etc., etc. Adjacency of one wire to another, number of bands of interest.

When someone has pruned lengths to his satisfaction by trial and error, in his own particular surroundings, ask him to take down the antenna and accurately measure all dimensions. And then copy it. There is a small probability you may be satisfied yourself. Your transmission line length and Zo will inevitably be different.

What do you anticipate saving from your efforts? A tuner ? No hope !

Just erect a single-wire random length dipole, with a balanced feedline of any sort, also of random length, get a tuner, and you will have an efficient radiating system which will give you ample satisfaction for a few months until you become bored (like most of us) and develop a longing to try something else.

Having learnt something you will be then be free to occupy your mind on more important (to you) matters. And your tuner will ALWAYS be useful.

Having said all that, you can be just as insanely happy struggling to tame your unruly, entirely incomprehensible multi-band, multi-wire dipole.

Have you contacted them to see if they have a tune up procedure?

Never seen one of these, let alone used one, but what I would do would
be to tune 20 meters first, since that would affect 40 meters.

40 Meters would be next, followed by 15 and then 10.

Jim

Small correction...Actually, that would be about 1.5 wave total
length. The 3/4 wave I meant as per leg, or half the total length of
the antenna. MK

But Reg, what I learned was not what I wanted to learn. :-(I thought
eight radials at 1/7 WL should do pretty well. After all, the vertical
was taller than the dipole and used more than twice as much copper as
the dipole. Where was my ROI?

>
> Roy Lewallen, W7EL

Very comical..... cyclic for the normal radiator is one wavelength
after which
it repeats.With a linear radiation a cycle will be uniform
acceleration AND negative decelleration.If one wants to achieve
Zukov's idea of point radiation,
uni directional, then a phase change must be made.
Critical coupling is when two radiators are parallel to each other
between which there is a capacitance where current flow chooses the
convenient point to 'cross over' which would be the best matching
impedance point.
With respect to my post, I was only probing around to see if a way
could be found to give 'gain' electrical units, not to make a
statement of fact. Lets face it,I am prone to name things or actions
that have already been named. If one feels that there is not a problem
created by gain not having units then there is no subject to discuss.
Thank you for your time.

I`ll try to explain the inexplicable. I wrote:
"One power ratioed to another is dimensionless."

CAM replied: "Not if the units are watts and horsepower."

I`ve contested in this group long enough to know better. The breadth of a statement must be limited or it likely faces a challenge. Cecil caught me with my guard down. With this group, I should have said, "the ratio of one power in watts to another power in watts produces a simple number or fraction devoid of units."

I think I know this crowd pretty well and, in another time with a different attitude, would have written more judiciously. But, I indulge in this diversion when I`m tired, sleepy, tipsy, etc., as well as times when I`m wide awake and alert. I wasn`t alert when Cecil caught me and exposed the chink in my armor. This is just a game. None of this is serious. No one is paying for any advice here.

Best regards, Richard Harrison, KB5WZI

Yes, you are correct that my antenna interests lie with multi
frequencies so it may be used on any frequency.As a matter of interest
I am constructing a homebrew antenna with variations to my norm that
hopefully will provide a similar thing but change front to back so
that extra gain can be achieved.This I have described in another post
incase this is of interest.
Participation in THIS thread was because I thought it was obvious that
'GAIN' which has no units, was giving considerable problems to many as
indicated by the length of this thread and the repeatableness of the
subject
and thus went beyond my capabilities in an attempt to assign units.
This aproach
obviously became comical.

>
> See Cecil`s multiband dipole matching scheme for something practical.

Yes, Cecils aproach is one way of dealing with phase reversal.
Unfortunately

his method by the use of his feed line has become an antenna SYSTEM
which he would be the first to admit. My method supplies a phase
change together
with adjustment providing for varying frequency use and thus remains
an antenna
and not a antenna system. This method in no way detracts from what
Cecil has achieved it is just that we have different interests and
different ideas.
Unfortunately my aproach brings to the fore gain measurement problems
to which this thread is related.

I may be late to the party...but what are you trying to do? That is, what
problem(s) are you trying o solve?

Freq?
Gain?
Form factor?
Bandwidth?
Etc?

You are calling up some nice tools to the fray, wondering why they are needed?

Best,
Chip N1IR

2058. Re: I just ordered a A 99 with gound plane kit

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-07 03:02:35 UTC
From: 'Doc <w5lz@cwis.net>
Message-ID: <3DC9D7CB.5B5CA602@cwis.net>
Source record: 131747

DJ,
The 'A99' is a good antenna, in general. They
sometimes have quality control problems, some not
being as well put together as others.
Gain is a comparative number, meaning that the
antenna in question is compared to a 'standard'
antenna of some kind, usually a 1/2 wave dipole.
Since the 'A99' ~is~ a 1/2 wave antenna, it has no
gain. Most 'CB' antenna gain figures are very much
over inflated (or they are comparing their antennas
to a beer can laying in the yard).
The groundplane add-on kit does make a very slight
difference, but I'm not sure that 'slight difference'
is worth the cost.
The 'range' of any antenna is subject to propagation
and how/where the antenna is erected, what's around it
and so on. No one can give you an accurate guess as to
the range of your set up, especially since it will be
changing all the time with propagation. At any one time,
you should get about as much 'distance' as any one else
does using the same kind of antenna.
'Doc

2059. Re: How to directly connect frequency counter?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-07 03:18:26 UTC
From: "Bob M." <xxxxx@yyyy.zzz>
Message-ID: <goecnTcBbd0dRlSgXTWcqg@comcast.com>
Source record: 131748

Remember that the whole idea of coax is that it's shielding the center conductor, so you really should have a problem getting enough signal in your shack. It's also a safer operation when the levels of RF energy are lower.

You can put a T connector in the line, but you'll need more attenuation than you've specified. One way that often works is to remove the center pin from the port on the T connector that's going to feed the frequency counter. This gives you a nice signal level but usually won't blow out the counter or affect your other amateur equipment.

And remember that your counter won't see anything unless you key up with a CW or AM/FM signal. SSB has no carrier to measure, and no sidebands unless you're talking or feed in a continuous audio tone.

Good luck.
Bob M.

I've wondered about this too. I've wondered what would happen, if, say, you strung out two dipoles intended for use at 7-Mhz, dipoles connected in parallel but physically at right angles to each other, one dipole longer and resonant around 5 MHz, the other shorter and resonant around 9 Mhz. Could you get a directional effect, that is, swing the radiation pattern by 90 degrees, by changing the settings on an antenna tuner back at the shack? I suppose the only way really to find out is to string out some wire in the back yard and get out some old neon bulbs or florescent tubes and see where the power is going.

This is contrary to my experience.
I had (some years back) a pair of ground mounted 1/4 wave verticals (half wave spacing) on 40 fed in phase with only 8 radials each. I had one elevated 1/4 wave with the base at 30 feet. The only radials were the three guy lines which were set to 1/4 wave plus 10%. I had a dipole at 40 feet.

The phased verticals never proved satisfactory except in the favored directions and I didn't have phase switching except for going out and actually changing cables. Due to the snow depth being above the bases they weren't the best in the winter either.

The one surprise was in the winter the noise (QRM) when working DX was usually quite a bit lower than on the dipole. The vertical "seemed" to reduce most of the stateside stuff by 1 or 2 S-units and pick up the DX by 1 or 2 S-units. That made the elevated vertical much better for long haul on average. Some times it was better than the dipole and sometimes it wasn't. Now, this could have been due to a quiet location which was well out in the country, but I still give credit to the verticals.

At the current location, I use sloping half wave dipoles which seem to work quite well. I have 2 on 75/80. One to the NE and one to the SW. I have one on 40 oriented to the NW.

If I had room I'd go try the phased verticals again, but elevated this time. One thing to remember is a vertical needs a lot of clear space around it.

2063. Elevated Radials idea

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-07 04:12:36 UTC
From: jhisson1@columbus.rr.com
Message-ID: <4c442fa0.0211062012.76fbc00b@posting.google.com>
Source record: 131752

Hi gang,

I have been looking in the back yard for some ideas about putting up a vertical antenna... I will have a tower, so I will have a beam. However, having a vertical may help me out with having a good, all-purpose, go-to omnidirectional antenna.

Here is my idea.... my back yard is about 75' by 50'. I was considering putting up a 5BTV vertical up at about 10 feet. I would buy some rotator cable to put up 4 radials for each band. (I would have to probably bend the 80M radials to make it fit) With it being 10 feet high, that would keep the radials out of the reach of little hands (and me running into it). I would tie off the radials in four corners using the fence (or just have 4 poles in the ground away from the fence) Anybody have a similar arrangement? How has it performed for you?

Also, if I used a vertical dipole instead, (like the Eagle DX) would radials improve the performance of the vertical dipole? I have a friend that is willing to sell me his for about 50% of the new price.

Thanks.... setting up (and planning) antenna systems is a ton of fun!

> to another power in watts produces a simple number
> or fraction devoid of units."

You could also say that, "the ratio of one power in watts to another power in *HORSEPOWER* also produces a simple number or fraction devoid of units."

For example:
1 horsepower / 1 watt = 746 (period - no units - dimensionless)

Obviously when you strike out the "watts/horsepower" units, you need to throw the number 746 into the mix somewhere appropriate to compensate. But the final result is, as you originally said, "dimensionless".

So long as your two values (numerator and denominator) are both for the same physical parameter (like power, or distance, or time, or mass, or anything else that God/Nature invented), the ratio will be, as you say, a simple number or fraction devoid of units. Feel free to use any pair of man-made units you wish (watts/horsepower, miles/km, seconds/weeks, kg/slug, etc.) so long as they measure the same paramter - the final result is still devoid of units and is dimensionless.

The only time you've been wrong is when you thought you were wrong - when you were wrong because you were actually right. The "Touch&#65533;" was actually a miss.

Sounds like a very typical installation. But, just how important is it that the radials be 'tuned' to each band above what would be considered typical lossy ground? I've heard of some different magic lengths in such an application. Comments?
>
> Also, if I used a vertical dipole instead, (like the Eagle DX) would
> radials improve the performance of the vertical dipole? I have a
> friend that is willing to sell me his for about 50% of the new price.

I don't know the particular antenna but if it is a true dipole it shouldn't need radials to perform. That leads to the question....what is the effect of good ground versus lossy ground underneath such a vertical dipole? I don't know how one would physically connect the radials so consider them simply in the field. Since there is "no" radiation off the tip ends of the dipole, theoretically it would be moot, but at a height where the feedpoint is somewhere in that 1/4-1/2 wave window it seems there would be some effect. Seems like it would carem a nice low angle off to a higher angle??? Would "good" ground underneath actually impair this antenna for low angle radiation?

Now that my curiosity is piqued....picture this situation....7 MHz 1/4 wave vertical antenna, 20 feet up with 3-4 radials. Below that set of radials, say 10 feet below, another set of 3-4 radials. Any advantage here by having the second set?

A bit late with this, but here's one that works.
I recall a tennis ball cannon, made of several beer/soda cans put together.
Small hole in bottom can.
Insert tennis ball, squirt in a bit of lighter fluid/naptha and light.
'Poof!' goes tennis ball.
A hunk of steel conduit or similar with a cap on one end, and ball that
fits barely snug inside pipe should work similar.
Denatured alcohol might also work as a propellant.
Be sure to keep face and other exposed flesh away from end of barrel/tube
when firing.
A light fishing line should work as starter line.

Note, I assume no responsibility for local laws regarding these things, as
laws vary quite a bit.
I think I like the arrow idea better...

Source record: 131760

Hi Cecil,
you just answered the question, yes the 50 ohm seen by the generator is due to the multiple reflections of v & I at the discontinuities. so after steady state has established the generator sees an apparent 50 ohm load.

once that steady state occurs (one could argue that that doesnt happen till infinite time as the line is lossless so refelctions continue, but lets be a little practical) the volts at the generator end of the 150 ohm line add up to be 70.71V 0 deg and the current is correspondly 70.71/50 A 0 deg.

the voltage at the 50 ohm on the other end is the same 70.71V and 180 deg relative to the generator end.

an inline power meter (really a voltmeter and again lossless) is manufactured with the assumption that the generator is matched to the line, ie the generator is 150 ohm as well as the coax. thus the meter sees the incident voltage and the reflected voltage. here we do not have that situation, both ends are mismatched. what you are seeing is what the meter has been made to read with the given assumption of one end matched.

and if it was placed inline would it see 133 and 33? or would it see 33 and 33?

Friend of mine had problems with tv channel in upper
portion of UHF region. He is not amateur, but otherwise
very handy with technology. When I visited his house, he
presented UHF rhombic antenna to me. He had found formulass
from some old tech. handbook!! The antenna was constructed
just how it should be, but was not working.

The impedance match was wrong (75 ohms) and feedline
unbalanced, but still it should have performed better.
The size of one diagonal was 5 lambdas, witch should
provide abt. 12 dbd . the gain was lousy and directional
pattern was not sharp. Could that be only due to wrong
impedance match ? Havent ever seen rhombic solutions
in UHF region, usually HF point-to-point and of course
that great rhombuc farm of late W6AM.

My 40m vertical was originally ground-mounted with 8 buried radials.
When I raised it by 20ft and installed 8 elevated radials, the 8
buried radials remained and didn't seem to help. Since they were
not connected to the rest of the antenna and were detuned by the
ground, I doubt much current was flowing in them.

Nope, a Bird wattmeter, for instance, doesn't care what the generator impedance is. All it assumes is that it is operating with a Z0=50 ohms, i.e. that the ratio of Vfor/Ifor is 50 ohms resistive and that the ratio of Vref/Iref is 50 ohms resistive. It samples both the total voltage and total current and uses vector addition to separate out the forward and reflected components.

No such assumption is made. There are assumptions made, but that is not one of them.

I don't think so.

> He would say the dimensions of that 746
> are watts per horsepower.

The "watts" and the "horsepower" are on the other side of the equation. The "746" has been inserted into the math so that those units may be cancelled out. 1 horsepower over 1 watt does not directly lead to the answer 746 watts per horsepower.

Taking this topic back to antennas gain, if the two measurements that you are comparing are 1000 dBm and 1 watt (for example), then which of the following is the 'right answer' for the ratio of the two power measurements as might be applied to answer a question about 'gain' ?

a) 1000 dBm per watt
b) 0.001 watt per dBm
c) 1.0
d) 0 dB
e) All of the above

In order to give you time to think, I'll put the answer in another posting.

> c) 1.0
> d) 0 dB
> e) All of the above

ANSWER:

Both a) and b) are 'true' statements, but if you supplied them as answers on a test, then your professor would chuckle. They are not the 'right answer' to the question. They are true statements about conversion factors, but that doesn't make them final answers to the question about power ratios.

Both c) and d) are correct answer to the question about the ratio of the two power measurements (1000dBm / 1 watt). You will note that both answers are dimensionless, unitless numbers (dB is not a unit).

e) isn't right either.

I trust that the parallel to the horsepower and watts is clear. I've simply replaced horsepower with dBm for this example to bring it back to antennas and make it more clear.

If someone asks for a ratio of two powers (in whatever units), then they should be expecting a number (unitless) for the answer. If your answer looks more like a conversion factor ("746 watts per horsepower"), then you're not finished yet.

Your professor might give partial credit, once he stopped laughing.

> Best,
> Chip N1IR

Chip the problem I gave myself was solved many,many years ago.
What I wanted was an antenna that was rotatable,capable of operating
on
any frequency. directive,inexpensive and light, and ofcourse we all
want the extra
gain.This particular antenna is meant to add some niceties to the old
design
with the addition of capacity hats, element longer than the norm,
weather protection for the variable capacitor. (The motor is not
homebrew)
What interests me most of all is the addition of shielding some of the
radiation for pattern purposes. If this operates as I think it will
then I will be adding a similar second element where the element
spacings will change with frequency.
All this should get me thru the winter Hi.
Note the capacity hats are 6 inches radius NOT 6 inches diameter.

I have no intention of dwelling on the 'gain' of this element since
it raises the ire of so many.(gain of a dipole over a dipole over
whatever!)
Regards
Art

Greg wrote:
"An inline power meter (really a voltmeter and again lossless) is manufactured with the assumption that the generator is matched to the line."

Generator match to the transmission line is of no significance to the line power measurements in a Bird wattmeter.

Reflection at the generator is ignored by an inline power meter. It becomes part of the incident power.

Reflection from the discontinuity opposite the generator produces reflected power sensed by the meter.

Were the load matched to the line, there would be no reflected power.

Impedance on a mismatched line varies with extent of the mismatch and distance back from the discontinuity. The inline power meter ignores the impedance variations produced by mismatch. the only impedance significant to the meter is Zo. That is because the meter looks only at the power traveling in one direction at a time. The power traveling in one direction sees only Zo in the line.

Consequence and proof of the above is that power can be measured anywhere along the transmission line and indicates the same value except for line loss.

Best regarda, Richard Harrison, KB5WZI

>are watts per horsepower.

It's unlikely that he did, because watts and HP are both units of the same thing - power, or energy per unit time. Therefore they both have the same dimensions, so when you divide one by the other, all the dimensions on top and bottom of the fraction will cancel, and you're left with a dimensionless pure number - a simple conversion factor.

To explain the difference between units and dimensions...

All everyday units can be reduced to some combination of a few fundamental quantities: mass, length, time, electrical current or charge, and absolute temperature (plus a few others, not relevant here).

The dimensions of any physical quantity show how this is done... where it comes from, if you like.

The units on two sides of an equation (eg 746W equals 1 HP) can be different, but the dimensions *MUST ALWAYS* be the same on both sides - because no two physical quantities can be equated unless they are fundamentally the same.

There are many different units of power: watts, HP (electric, boiler or metric - each slightly different), calories/hour, BTU/sec, joules per lunar month and so on... but they *all* have the same dimensions: energy per unit time. That means the conversion factors between them are always pure numbers.

From mechanics, the fundamental dimensions of energy are (Mass * Length^2 * Time^-2) or M*L^2*T^-2 for short, where ^ means "to the power of". So the dimensions of both watts and HP are M*L^2*T^-3.

Coming back to the original topic, gain is always a pure number, because it's the ratio of something like the power density, divided by the *same* thing produced by a reference antenna. The dimensions on the top and bottom of the fraction cancel, so gain is dimensionless.

You can also convert gain into dB. Decibels are a unit - but a dimensionless one.

Bill M wrote:
"Below that set of radials, say 10 feet below, another set of 3-4 radials. Any advantage here by having that second set?"

Some, but that`s not the best use of radials.

Purpose of elevated radials is capture of the essential displacement current between the vertical radiator and its ground return to the radio. Any of this current returning through the earth is likely to produce loss. Elevated radials tend to hide the earth from this displacement current. So, the additional radials would work better up close to the radiator, more capacitance between radiator and radials, less capacitance between radiator and the earth. Also, the placement should be equally interspersed between the existing radials so that balance is maintained to minimize radiation from the radials and so that shielding of the earth from displacement current is more complete. More radials almost never degrade an antenna and often help, especially at low antenna elevations.

Harry, VE3GRO wrote:
"Could you get a directional effect by changing the settings on an antenna tuner back at the shack?"

Follow Cecil`s advice and explore for yourself. But, the short answer is you can affect the directional characteristics of a directional array back at the shack if your controls change the power ratio and phase between elements as broadcasters` controls often do. Ham tuners usually only affect the combined antenna signal and have no effect on directional characteristics of an array.

The dimensions of that number "745.7" is watts per horsepower. Without
those dimensions, the other dimensions in the equation would not cancel.
How does one convert X horsepower/watts to a dimensionless ratio. Why,
multiply by 745.7 watts/horsepower, of course.

Jyrki wrote:
"The gain was lousy and directional pattern was not sharp."

Environment affects antenna performance. Rhombics, in the clear, 4 or 5 wavelengths on a side, and about twice as long as wide can be great performers at any frequency.

An Australian built Arnold B. Bailey`s rhombic from "TV and Other Receiving Antennas" and posted his satisfaction to this group.

Bailey`s horizontal rhombic antenna:
Size at 200 MHz: Two #10 wires each 36 feet long, separated 18 feet at midpoint, overall length 31 feet.
Transmission line: 300 ohms balanced
Resistance at center frequency: 600 ohms
Antenna average surge impedance: 600 ohms
Termination resistor: 600 ohms
Gain at center frequency: 14.5 db (or less)
Frequency bandwidth: 1 db down, 30%

I`ve erected many horizontal h-f rhombics and never been disappointed.

Best regards, Richard Harrison, KB5WZI

|from some old tech. handbook!! The antenna was constructed
|just how it should be, but was not working.
|
|The impedance match was wrong (75 ohms) and feedline
|unbalanced, but still it should have performed better.
|The size of one diagonal was 5 lambdas, witch should
|provide abt. 12 dbd . the gain was lousy and directional
|pattern was not sharp. Could that be only due to wrong
|impedance match ? Havent ever seen rhombic solutions
|in UHF region, usually HF point-to-point and of course
|that great rhombuc farm of late W6AM.

The transmission line mismatch and unbalance are negative factors,
especially the unbalance. However, the rhombic is in my opinion a
very poor antenna particularly from the standpoint of minor lobes.
The Laport rhombic purported to improve the minor lobe problem by
using multiple rhombics in echelon.

I have modeled some of these using information from his original paper
and have not yet found the results to be particularly favorable.

Antennas for the upper UHF channels are difficult. Hams have used
Yagis, particularly loop Yagis as high as 1.2 GHz. These might be an
answer for your friend. One method of loop construction has the
advantage of a built-in balun, which he should use regardless of what
kind of antenna he uses.

Another option would be a dipole + trough reflector.

Ian, G3SEK eloquently wrote:
"The dimensions of any physical quantity show how this this is all done..."

To some, we must appear as the blind Indians describing an elephant.

Inches and centimeters may be chosen as units of length (the standard, I believe, is a precise meter bar guarded somewhere in Paris).

If we choose inches and centimeters as umits of measurement, yards and meters become dimensions because a dimension is a synonym for size.

A measure of 36 inches is one yard. A measure of 100 centimeters (units) is one meter, a dimension.

2096. Questions on Wire Antennas-Advice

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-07 16:58:17 UTC
From: kg6zi@yahoo.com
Message-ID: <3f36625c.0211070858.37b18e24@posting.google.com>
Source record: 131785

Good Morning,

Now, between questions and opinions, there has to be something in this one for everyone :)

I've just about finalized my ideas for the two wire antennas I will put up hopefully before the end of the year (unless the rainy season comes early). Before I start scrounging up materials and lining up help for the TV mast party, I thought I'd briefly describe what I want to do and solicit your comments and opinions. I have a specific question or two about one of the antennas that involves a choice in placement, so hopefully I can get a good answer or two on that.

The first one, whose configuration is pretty much set, is a tilted delta loop of about 350 feet of 12 AWG in roughly an equilateral shape with the point up. It will be fed from a lower corner with open wire line to a air core choke balun, then into the shack through an SPC type of transmatch. The apex will be about 65-70 feet high with the base between 10 and 15 feet above the ground. It will be oriented broadside N/S. Its support by the way is a 50 foot TV mast on the roof, with non-metallic guys except on the lowest ring. I had excellent results with a very similar antenna about 2/3'rds this size, but with the base even lower...about 6-8 feel in that case..so I'm hopeful about his one. I would enjoy any and all comments, suggestions and discussion on this one

The second one has a choice to be made before I finalize its configuration. In any case, it will be a simple dipole, 12 AWG, center fed with open wire line through a coaxial choke balun to the shack and an SPC design transmatch. It will also be oriented broadside N/S (no real choice on either orientation).

Option A has a length of about 100 feet and both ends at about 50 feet above the ground, i.e. essentially a level flat top.

Option B has a length of between 125 and 130 feet, one end at the same 50 feet, but the eastern end will be about 15' above the ground..i.e. a sloper.

I'd be particularly interested in how the two options might compare on the lower bands (80/40). On one hand I can have the height for the whole length, but only 100 feet long, the other has more length but a lot closer to the ground on one end. Comments?

Thanks for your time. Please feel free to email direct.

Dennis

"CAM"
> Thanks for proving that the conversion factor has the
> dimensions of watts/horsepower.

Cecil, you're as slippery character as I've ever seen.

Richard wasn't looking for a conversion factor ! He was looking for a ratio of power measurements. The conversion factor helps you to cancel out the units leaving a dimensionless number - in this case the answer bears a striking resemblance to "746" ONLY (!!!!!!!) because the input data was selected as 1hp in the example.

If we had selected 2 hp for the example then the correct answer would be 1492 (a dimensionless number). That would make your answer of "746 watts per hp" even more obviously wrong (for those that need it to be more obvious).

Review my previous posting - try answering the quiz.

If required, I can develop an even more clear example (using antennas and watts and hp) that will make it even more clear that you were (and are) wrong in the original thread that I won't bother to repeat again. It shouldn't require it, but I'm willing to go further if required.

> The dimensions of that number "745.7" is watts per horsepower.

Sigh...

If 746 is a conversion factor, then yes - you're correct. It has some dimensions after it.

BUT - if it just happens that the example used ONE (!!!!) hp, then it shouldn't come as any surprise that the nmerical answer (746 to round it off) happens to look like the same number as the conversion factor.

But the answer to a ratio of powers question (like Richard's) is a dimensionless number.

Try again with 2hp and see how your argument stinks.

I'm wrong when I say that conversion factors are not dimensionless?
That's the only thing I have said.

If I tell you that my 10 horsepower motor will result in 5kW out
of the associated generator, and ask you for the efficiency of the
system, you are telling me that the efficiency of the system, a
dimensionless number, is 5kW/10 Hp = 0.5k, a dimensionless number???
It is NOT a dimensionless number and neither is the conversion
factor that will eventually turn it into a dimensionless number.
If you haven't canceled the dimensions, it is NOT a dimensionless
number. If two powers are provided in different dimensions, their
raw ratio is NEVER dimensionless.

> 'Doc

Sure, but try supporting the 42 ft tall vertical double extended zepp
all in one piece. Not going to be easy. The ground plane version lets
you use radials instead of the solid bottom 5/8 section. The gain on a
"pure" dual 5/8 antenna is slightly better than the ground plane
version. But the ground plane version is much easier to deal with. MK

2106. Re: Rhombic for UHF

(Richard Harrison) wrote:

|Jyrki wrote:
|"The gain was lousy and directional pattern was not sharp."
|
|Environment affects antenna performance. Rhombics, in the clear, 4 or 5
|wavelengths on a side, and about twice as long as wide can be great
|performers at any frequency.
|
|An Australian built Arnold B. Bailey`s rhombic from "TV and Other
|Receiving Antennas" and posted his satisfaction to this group.
|
|Bailey`s horizontal rhombic antenna:
|Size at 200 MHz: Two #10 wires each 36 feet long, separated 18 feet at
|midpoint, overall length 31 feet.
|Transmission line: 300 ohms balanced
|Resistance at center frequency: 600 ohms
|Antenna average surge impedance: 600 ohms
|Termination resistor: 600 ohms
|Gain at center frequency: 14.5 db (or less)
|Frequency bandwidth: 1 db down, 30%

I just modeled this using Eznec. It isn't specified how high above
ground this is so here are the free-space numbers at 200 MHz.

Gain: 12.8 dBi
Front to sidelobe ratio: 8.45 dB.
Feedpoint Z: 630 +j 14

Within the claimed BW of 30%, the first sidelobe is down only 6 dB at
230 MHz.

If you live in a location such as mine where multipath is really bad,
this would not be usable.

Units of dimension are well-defined. A unitless quantity has no dimension.

Gain has no dimensionality. It is a number. That's all it is.

>NEVER dimensionless.

Sorry, CAM, but your recollections of "units" and "dimensions" are cross-wired.

It is logically impossible to quote quantities of power in any different dimensions than (M*L^2*T^-3) - because that set of dimensions belongs uniquely to power.

There are many possible sets of units for power, but they *must* all analyse down to that same basic set of dimensions - or else they'd be units of something else.

Therefore if two power levels are provided in different units, their raw ratio is *always* dimensionless - a simple number, a conversion factor.

The value of that factor depends on the pair of different units that it converts between. You can call it "watts per horsepower" to remind you which units are involved, but both watts and horsepower share the same set of dimensions, so their ratio is still just a number - dimensionless by definition.

by the letter of the law, yes. your ham radio is not type accepted for that service since it falls under a different section of the fcc rules. as a practical matter the fcc doesn't have the manpower to even run down the web sites who openly advertise 30kw mobile amps for cb and the truckers who infest 28085 and 28535 daily.

> conversion factor) and see how your argument stinks.

That's stupid. Show me exactly where (quote me if you please) I agreed to your bracketed phrase "(without a dimensioned conversion factor)" - key word being "without". Duh.

Richard's original statement about the ratio of two powers being dimensionless was, and always will be, correct. Your attempted correction was wrong. So was Richard's unnecessary "Toch".

Any necessary conversion factors along the way DO NOT change the fact that the final answer will be a ratio and will be dimensionless.

You're being fairly consistent in trying to ignore my proofs along the way. Why don't you answer the quiz that I previously presented ? Oh, I see, because then you would have to admit that you were wrong.

I have been away form the group a long time.

Hamfests sales at flea markets being what they are, lousy I want to keep going but it pays better to buy at ham fests and sell on ebay. I want to have something to sell at the ham fests and well made reasonably priced antennas seem to do reasonably well for me in the past.

I have 3 antenna designs that work and have been range tested side by side with commercial products using corn field ranges and they pass a reality check and I need to know what patristic to use for the center insulator in dipoles (low voltage, high current) and traps where the voltage and loss are more critical. UV and weathering are also an important consideration.

I can get all the facts from table, but in a real world compromise what have others found to be the best solution for them. Electrically styrene is of course the best but practically it useless. Price wise PVC is great but UV eats it up. I expect Nylon or one Teflon or on of the others is the all around best solution

Thanks for your help

The FCC is pretty lax on enforcement, especially for someone running "legal" power on the CB band with ham equipment. You'd have to do something pretty outrageous to get their attention, and then at worst you'd probably receive several desist orders before sterner action is taken. One caveat -- if you have any FCC license, you can expect to forfiet it if you're caught.

FCC has done some enforcement in recent years, but there's a lot more to be
done. FCC is complaint-driven - if someone complains, and hands the FCC usable
evidence and information (like audio tapes and exact date/time/frequency
reports) they will try to enforce the rules.

One BIG difference about a ham vs. the general public is that the ham is FCC
licensed, and is supposed to know about the rules. When you and I applied for
our licenses (new or renewed), we agreed to abide by ALL FCC rules as a
condition of the license. So FCC has a leg up on enforcement, compared to
unlicensed persons.

Same things go for use of, say, modded VHF/UHF rigs on FRS/GMRS, MURS or the
various public safety services.

I would like to ask the following questions? Assume that you have a mobile with an 8 foot vertical whip with a high Q loading coil near the center that is resonant at 3.9 mHz. Then with a tuner near the antenna you tune for max power. Later you replace the loaded whip with an 8 foot section that has no coil, just a whip. Which one will have the best efficiency and why? Later we QSY to 3.8 mHz and do the same, same question.

Hi Gordon--

Black Delrin works well for RF insulators as long as you don't need to glue anything to it. Black ABS isn't quite as good, but will take glue better.

Can't you just buy this?

If not, may I submit that having someone provide an answer is a poor way to get a conceptual sense of antenna design.

Think about how those OTHER guys came up with those ideas...

Hint:

Think CURRENTS.

Think LOSS TANGENTS.

Think GEOMETRY.

Only thing I know is the Icom AH2B. You can buy the whip only for this mobile antenna; the whip is 8.2 feet long. It does cost $119, though !!!

That's kinda apples and oranges. The biggest factor would be the Q of the loading coil in the whip vs. the Q of the coil in the tuner (assuming it's an L-network). I would think that a big airwound coil in the center would be a lot higher Q than those used in typical mobile tuners like SGC.

Assuming equal Q...I don't know that there have been any definitive studies of base loading vs. center loading in terms of efficiency. I have seen studies that show mid loading slightly better...and others that show it equal. The base loaded version should have slightly less bandwidth, however.

If both coils are tuneable to resonance, then the efficiency would be similar...although I guess theoretically the lower frequency would be marginally worse since the whip is a fixed length.

Henry,
The loading coil will get more of the signal nearer to the top of the antenna which means it is higher above the car body. This is why screwdriver antennas and texas bug catchers work so well!

Les,
AA4F

The feedpoint impedance of the loaded antenna will be in the neighborhood
of 20 ohms resistive. That is easy to match with a tuner. The feedpoint
impedance of the whip is about 0.5-j2000 ohms. The losses in the tuner
matching such an impedance would be substantial. I have actually measured
the difference in efficiency between a center-loaded mobile antenna and
a whip driven by an SGC-230. The difference was about 12 dB, i.e. the
center loaded antenna was 16 times more efficient than the whip plus
autotuner.

Hmm, this sounds like instances where the neutral line is in poor condition
at some point.
Otherwise. there should be no voltage potential between the neutral and the
actual ground.
But there may have been some electrolytic action causing the problem, and,
as I said, a faulty neutral.
This is why it is also important to have that ground in good condition, as
well as an actual connection in your main panel box between the ground and
neutral..

Hi again all,

Rather than me continue to try and convince you there is only 100W in that 150 ohm line, how about you have a go to convince me there is 133W.

There is 100W and there will be VARs - thats a hint
At any point on that line there is 100W and quite a few VARs to boot as it's mismatched at both ends

A wattmeter is a misnomer. The only true wattmeter is a calorimeter n(or bolometer) load, where the power is actually measured.

Inline meters (as far as I'm aware) only measure current, and the amplitude at that, not the phase. I've not seen one that does, but I'll concede there may be one.

As you indicate above, the reflection at the generator is considered part of the incident . however that reflection affects the impedance presented to the generator as was identifed in earlier posts. thus the steady state is created once more.

Those measurements are only usefull when the source impedance is matched to the line. The forward measurement ON THE LINE is assumed to be incident from the source, not from reflections at the source end of the line. Thus the meter references the reflected current to the incident and displays on meters calibrated with respect to Zo.

gcd wrote:
> Rather than me continue to try and convince you there is only 100W in that
> 150 ohm line, how about you have a go to convince me there is 133W.

Be glad to. Imagine a one second long piece of lossless 150 ohm transmission line with a 50 ohm load and a 100w source. One second after the transmitter is keyed, the line will contain 100 joules, i.e. the output of a 100w transmitter for one second. There are no reflections yet and no power has reached the load. At the end of two seconds, the transmitter will have output 200 joules. 75 joules will have been delivered to the load and 25 joules will have been reflected from the load since Rho=0.5. That means that 125 joules is stored in the line. Take it second by second and you will see a buildup to steady-state conditions. When steady-state is reached, 100 joules/sec is still being sourced, 100 joules/sec is being delivered to the load. 133.33 joules are stored in the forward wave on the way toward the load and 33.33 joules are stored in the reflected wave on the way toward the source. The transmitter has sourced 166.66 joules (with the voltage and current in phase) that have not yet made it to the load. During any one second period. 133.33 joules/sec of forward energy will pass a forward power measurement point. 33.33 joules/sec of reflected energy will pass a reflected power measurement point. The energy in the forward and reflected waves has been generated by the transmitter as watts, not vars. The V*I*cos(0 deg) equals 133.33 joules/sec for forward power. The V*I*cos(180 deg) equals 33.33 joules/sec for reflected power.

Are you aware that a transmission line forces certain conditions upon waves? For any single wave, V and I are either in phase or 180 deg out of phase, i.e. the cosine of the angle between voltage and current is equal to one, V/I=Z0, Power in watts (not vars) = V*I = V^2/Z0 = I^2*Z0.

2151. Coax ground

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-08 15:11:22 UTC
From: Bill Ogden <ogden@us.ibm.com>
Message-ID: <3DCBD41A.C5A6C639@us.ibm.com>
Source record: 131689

I plan to install a half-sloper on a crankup tower. The half-sloper will be at the top of the second section of a TX-455 tower. (Since there is only a quad at the top, I assume that I will need the top tower section as part of the "counterpoise"). The various cables up the tower (coax to a quad, rotator, coax switch, coax to the hanf-sloper) will go through the standoffs outside the tower.

The tower itself is the primary radiator for the half-sloper. Is the outside of the coax effectively part of the radiating element in this case? Do I need to connect the coax shield to the bottom of the tower?

I also want to install a ground panel with lightning bypass units (coax, rotator, coax switch) just outside the house at the cable entry point. This is about 50' from the tower. Each coax connection is a point of failure (especially in my case because I am not very good at installing connectors). I hesitate to put coax connectors at the bottom of the tower AND at the house cable entry point unless I really need them. (There are also connectors on the coax switch mounted on the quad boom.)

The common reference books all say that the coax should run down the inside of the tower. The good people on the Towertalk reflector almost all use the cable standoffs in the case of crankup towers.

Greg wrote:
"---how about you have a go to convince me there is 133W."

A uniform transmission line has uniformly distributed series inductance and shunt capitance. An electrical pulse imposed on the line must move and its movement is current on the line. The line`s construction determines its L&C per unit length. These in turn dictate the current a particular pulse causes. It is the same voltage to current ratio for pulses of any shape or amplitude. So, it is called a surge impedance and in an ideal line it is a resistance. That is, the current is instantaneous with the voltage, it is "in-phase". The Zo, the surge impedance, is a a resistance (lossless). Resistance means the current is in-phase with the voltage. Its magnitude is 50 ohms, 600 ohms, or whatever as a voltage to current ratio.

When a voltage is applied to a point, the current depends on an impedance limiting the current and the difference of potential at the point. If a voltage of the same magnitude and phase exists at the point, there is no current imposed regardless of impedance.

Reflection from a load on a transmission line returns to the generator. It can add or subtract from the difference of potential causing energy transfer into the transmission line. This is effectively a changed impedance presented to the generator.

The reflection has nothing to do with the impedance enforced by the transmission line! The line only allows energy to be transferred in either direction at a voltage to current ratio of Zo.

There is a "forward power" and a "reflected power" because in-phase transfer is enforced by the line. Go to any good transmission line text for the reflection mechanics, Terman for example.

As Dr. John Fakin said, "A man convinced against his will is a man unconvinced still."

Bill Ogden, W2WO wrote:
"Each coax connector is a point of failure--."

There is vulnerability to moisture added to possible mechanical failure. You need a dry shelter for your connections. Wraps which never admit water can be made with electrician`s stretchy rubber tape and this is then topped with vinyl tape and doped with a good sealant. Game`s over when water enters a connector or splice.

Best regards, Richard Harrison, KB5WZI

Hi all,
Look in the phone book under plastic and glass. Plastic distributors
and companies that use plastic usually have a dumpster with scraps in
it. I have had good luck by asking the guy at the loading dock if I
can get a few pieces out for my project use. If they say no, come
back after hours and leave a couple of bucks for the pieces you take.

Glass shops also have plastic and sometimes have small cutoffs that
they can't sell at retail prices. Always haggle with them.

Referring to an earlier post. Lexan is not bulletproof, just bullet
resistant. It can be penetrated with the right load. Unless the
lexan is installed properly it can also be blown out of the opening by
a large caliber slug. I have seen Kevlar used to make walls in banks
and gas stations harder to penetrate but never Lexan. Matter of fact,
if you have installed the drive thru window assemblies in banks and
gas station pass throughs as I have, you would know exactly where to
shoot to avoid hitting anything that would do more than slow down a
bullet.

One gas station owner covered the concrete block walls and attendant
area door with Kevlar and put bullet resistant glass in all the
windows around the cashier and a bullet resistant Lexan cash pass thru
window assembly in. Only thing he did not do was put anything behind
the pegboard under the pass thru window. He thought no one would
notice it because it was covered with candy. LOL

"At any point on that line there is 100W and quite a few VARs to boot as it`s mismatched at both ends."

See, that`s one of those too-broad statements. At every quarter-wave back from a mismatch, there is a phase-reversal. At these points, the reactance goes through zero. There are no volt-amps reactive (VARs) where there is no reactance.

You have plus and minus reactances on a mismatched line, but no negative resistance (the line wont amplify or remove loss). The resistance in a mismatched ideal line can cycle between zero and infinity, but it can`t go negative. See 1955 Terman, page 99.

Dennis,

On Optiopn-B, have you considered dropping both ends, and keeping it
symmetrical? That would keep a major part of it at a good height, and
neither end would be as low as 15'. I realize thar trees do not grow where
you want them to ...

> directional characteristics of an array.

You can build an "L-C" phasing unit fairly easily. You can make one
from a L net tuner, if you swap a few wires around. I had a diagram to
make one somewhere...
But in the real world, I preferred coax lines to change direction when
I used phased arrays. If you want a directional effect from two
dipoles, I always ran them parallel, and both tuned to the same freq.
I've never tried off freq dipoles at right angles. But offhand, I
don't think it would pan out too well. You can run a turnstile, and
feed in three different ways, and have three sets of patterns. That
will work fairly well, but no real gain over a single dipole unless
it's used on a higher than normal frequency. And then in that case,
you would need to use ladder lines instead of coax, to avoid line
losses.
Running parallel dipoles phased will give you performance nearly equal
to a two el yagi. Maybe 4-5 db gain over a single dipole, and a decent
f/b ratio. 20 db f/b was about average when I ran those on 40m. MK

I think you're saying both (the dipole and the loop) are "half way"
decent for 80....but then I don't understand why they wouldn't be as
good or possibly better (more wavelengths of wire at 40 than 80) on
40..especially for the loop and considering they're both fed with open
wire and a tuner.

Can you explain?

Even drawing pictures, or using models with water to show wave action will never present electronics, antennas, radios, or computers in a way the layman will understand.

Even the flashlight, which works like a very efficient two element, or even three element doens't give them an anology they can understand because they don't understand how the reflector works in the flashlight. They think they do, so they say it makes sense, but to them it works because the reflector in the flashlight is shiny and reflects the light. They have no concept of focus and wave fronts.

It's not that the concepts are difficult to understand, it's just the average individual doesn't think in those terms and isn't willing to take the time to learn.

Actually the FCC has required a type acceptance for commercial Ham Rig for some time.
The difference is we can modify the Ham Rig and it is still legal (as long as the emissions are clean and on frequency)

> type accpeted. also CB radios must not be controled by a VFO. or VFO

In todays radios, this is kind of a moot point as both the ham rigs and the CB rigs use a phased locked loop for frequency control. Both are programmed. In the Ham rig the steps are very small, but they are still steps. In the CB rig they are discrete, specific frequencies for each channel.

BE VERY CAREFUL ABOUT GROUNDING to a WATER SYSTEM!
Make *certain* the water system is really grounded. Many new water systems may be metal on the inside of the house, but the connection between the house and main is likely to be plastic. The same is true of gas lines.

I just rewired the house, had the feed changed from overhead to underground and the service from an old 60 Amp split buss to a 200 Amp with a secondary feed from the 9KW generator through a 60 Amp box/transfer switch.

The inspector like the instalation, and the only changes he wanted to see were the grounding added to the gas line and to the water line. He said the national code required both. I pointed out that although both were metal inside the house they were both plastic outside. He said no, the water line coming in had to be metal. I got out the flashlight, and showed him the end of the plastic water line coming in and fastening to the *brass* valves and metering. I left the gas line grounded (it's supposed to have a small static ground molded in), but we both decided that with a plastic water main, the house was far safer without grounding the electrical system to an ungrounded water system.

Stop and think about the ramifications of grounding to your house water system when it is not grounded.

> (There are also connectors on the coax switch mounted on the quad boom.)

There is a very good page (which I unfortunately have forgotten the URL) on tower and feed line grounding. They do not use connectors at the bottom of the tower, but they do strip the insulation off the coax and ground the brade to the tower just a bit above the base. This allows the coax to make a sweeping turn to come to the house.

There is no connector, but there is the added difficulty of sealing the braid and connection. I'd use "liquid electrical tape", but it's still difficult to get all the spots.

Ground cables come off each leg of the tower in a sweeping curve to the first ground rod and then on out to each of the other ground rods in the system.

The lightening arrestors come before the cable enters the house, or right at the bulkhead if you come in straight. If you make a turn the bulkhead is installed prior to the turn giving the lightening the least path of resistance. (the turn needs to be quite close to the entrance.)

>
> The common reference books all say that the coax should run down the

I have the coax taped to the outside of the tower, but I do not use the tower as a radiator.
Most of the commercial installations I've seen use cable trays, or mounts on the outside of the tower.

If you are going to use the tower as a radiator, you may have a problem with the coax on the outside, but being a crank up you may have problems with it on the inside.

After some thought, I can't think of any good reason not to ground the water system. What are the negative ramifications you're referring to?

Obviously the water system shouldn't be used to provide the ground connection if it's plastic, but assuming that your power system is otherwise properly grounded, what's the harm in connecting the water pipes (or any other metallic objects) to ground?

Source record: 131708

Bill,
The coax shield is not (or shouldn't be) a radiating
part of the antenna. No, I wouldn't ground the shield
at the bottom of the tower.
If you're using one of the commercially made ground
panels, do what the instructions say to do. If you're
making your own ground panel, it wouldn't hurt to take
a look at the commercial systems to see how they do it.
I would think that a 'ground' at the base of a tower
wouldn't be needed since you'll be handling it through
a grounding panel anyway...

"Within the claimed BW of 30%, the first sidelobe is down only 6 dB at 230 MHz."

No quarrel with EZNEC. It is assumed a 200 MHz TV antenna is many wavelengths above the earth, unless it is rabbit ears atop the set. 230 MHz is within the 30% bandwidth of the rhombic. 30 degrees off the azimuth of the rhombic is outside the beamwidth of the rhombic, which is no more than plus or miinus 15 degrees. Bailey gives the patterns. The first sidelobes are at about 40 degrees either side of the rhombic heading and they are down about 10 db.. A reference dipole would be down only 3 or 4 db at 40 degrees off heading, so the rhombic is at least 6 db better, should you have interference from the sidelobe direction.

The point is, where interference may come from is rarely know in advance. Directivity may be important. Gain and directivity are almost different names for the same thing. The antenna with the most gain has the most directivity.

The UHF rhombic recommended to be scaled from the 200 MHz rhombic may be rotated to put interference in a 50 db null!

Best regards, Richard Harrison, KB5WZI

A vertical such as a ground plane is OK for local FM work and strong SSB
signals.
For weak signal SSB/DX, ...I would say use a minimum of a 3 element rotable
beam (bigger if possible.) If all you can do is use rotatable dipole, that
is better
than nothing. Always use good low-loss coax and make it as short as
possible
to minimize rf losses.

I'm pretty sure my 2 S-units of vertical noise comes from the
power lines. My power company is Entergy. There's a transformer
on the power pole in front of my house. It has a ground wire
running down the pole. I cannot even receive a local AM station
with the portable AM receiver anywhere near that wire. My dipole
is relatively unaffected by the noise.

Loops are somewhat the opposite of dipoles. A two wavelength
loop is resonant with a decent feedpoint resistance. The
worrisome feedpoint impedances for loops are the odd
half-wavelengths. The even half-wavelengths are pretty
good for loops. That's why horizontal loops work so well
on the harmonic frequencies.

Do you want to work SSB or FM? The groundplane is only good for FM - SSB is horizontally polarized. About the smallest thing you would want is a 3 element beam. If you absolutely can't put up a rotator, then a Halo kind of thing. M Squared makes one. I can't recall what they call it, but it is a horizontal loop about 3 feet in diameter. The 6 meter SSB calling frequency is 50.125 MHz, although some people insist it is 50.200. The DX calling frequency is 50.110 MHz. My guess is that less than 10% of 6 meter activity is on FM. 6 meters is a good band when it cooperates. From New Jersey, I have worked almost 100 European grid squares, all SSB.

Here is a question that I have been wondering about.

What percentages of the total current do elevated radials really carry?
Where is current at that they don't carry? Is it in the ether between the radials or flowing
along/through the ground below?
Do the radials represent a low resistence to RF at a certain height and hence most of the RF takes
the path of least resistance?

|> power. Later you replace the loaded whip with an 8 foot section that has no
|> coil, just a whip. Which one will have the best efficiency and why?
|
|The feedpoint impedance of the loaded antenna will be in the neighborhood
|of 20 ohms resistive. That is easy to match with a tuner. The feedpoint
|impedance of the whip is about 0.5-j2000 ohms. The losses in the tuner
|matching such an impedance would be substantial. I have actually measured
|the difference in efficiency between a center-loaded mobile antenna and
|a whip driven by an SGC-230. The difference was about 12 dB, i.e. the
|center loaded antenna was 16 times more efficient than the whip plus
|autotuner.

Hmmm.

I modeled an eight-foot whip over perfect ground at 3.8 MHz.

1) Without any loading:

Zin ~ 0.4 -j1832

2) With an inductive reactance of 1832 ohm at the feed and assuming an
inductor Q of 200:

Zin ~ 9.6 - j0.6

Ignoring the effects of mismatch the efficiency is 4.0%. This is
basically the ratio of the 0.4 ohm radiation resistance to the ~9.1
ohm resistance of the inductor.

3) With an inductive reactance of 3465 ohm 50% up from the feed and
assuming an inductor Q of 200:

Zin ~ 20.7 + j0.6

Ignoring the effects of mismatch the efficiency is 4.4%. The
efficiency is slightly higher than with base loading because the
current distribution in the section below the inductor is improved but
this is offset to some degree by the higher inductor resistance.

There have been published studies that examined these offsetting parameters and determined that the optimum loading coil location is about 40-60% of the height of the radiator. (Without any top hat loading)

4) Without any loading but using an 'optimum' tuner at the bottom:

Effectively, the base loading inductor is moved inside the tuner and is the series element in an L-network. A 77.56uH inductor with a shunt 1686pF capacitor provides the match. With capacitor Q = 1000 and the same inductor Q = 200, the network loss is 96%, so the efficiency is 4%, nearly the same as before.

What case four proves, if Cecil's numbers are correct, is that the SCG tuner is *very* lossy.

In any case, there is a *very* hi-Q tuning situation; read *very* touchy adjustment procedure.

Of course, all of the foregoing is purely hypothetical since it assumes perfect ground. When the tens of ohms of ground resistance that exist between the vehicle and ground are inserted then the tuning gets easier and the efficiency goes further in the toilet.

Source record: 131622

Vertically polarized antennas are NOT just for FM on 6m. If you are working locally, (not via ionosphere), then yes, polarization is an issue. But if you are working sporadic E or regular F layer communications, then the polarization is not a significant factor, because the polarization off the ionosphere is relatively random. I have made hundreds of 6m qsos on ssb sporadic E with an R6000 vertical.

To work tropo ducting, tropo scatter, aurora and to a lesser extent meteor scatter, polarization is VERY IMPORTANT. However, if all you are going to do on 6 is sporadic E each season, then a vertical antenna will suffice.

One easy solution for both (if funds/rotors/space are issues)) is to have a ground plane as one antenna and a simple six meter dipole as the other. This eliminates > 20 dB of cross polarization loss in those cases where polarization is important. Aurora requires not only polarization matching, but usually gain/power combo. 100w to a 3 el yagi will work dandy for aurora, but a simple vertical is likely to be very disappointing.

During E season, (May thru June, sporadically) just about ANYTHING works quite well.

If you are going to be really serious about 6 meters, then a 3 el yagi is a minimum as noted by the other poster. If you are just going to dabble, then either a 6 meter dipole or a vertical or both are fine to get your feet wet with.

50.110 and 50.125 are the calling freqs (international/domestic respectively).

Six meters is dead 99% of the time, unless you work troposcatter and meteor scatter/aurora. When E season starts, the band opens nearly every day and sometimes twice a day with VERY big sigs!

Hope this helps, 73

> the most directivity.
> . . .

Gain and directivity differ only by efficiency, but this can make a major difference. For example, a Beverage antenna, which has low efficiency, has considerable directivity but low gain (compared to an efficient antenna). A vertical with very good ground system has less directivity but more gain than a typical Beverage.

The statement that "the antenna with the most gain has the most directivity" is true only if both antennas have similar efficiency.

Rhombics are typically 50% efficient, so more efficient antennas can have more gain while having less directivity than a rhombic. Conceptually, it's a matter of taking the power that's dissipated in the rhombic's terminating resistor and using it either to increase the gain for the same directivity (same beamwidth), decreasing the directivity (widening the beam) for the same gain, or any combination of the two.

It uses iron core toroids on 75m - don't know the 'Q'.

Hi Dan,

I've got an R-7000 and an 18AVT in the backyard. The manuals for both antennas indicated that you should adjust the antennas for minimum SWR starting with 10m and moving down in frequency until you get to the lowest band (40m or 80m depending on the antenna). readjustment might be the way to improve your figures here.

I'd also rig up a radial system using TV rotator wire. 3 or 4 strand, one line for each band and use 3 or 4 radials.

Good luck,

Bill, W4WNT

Or the most directive is also the more efficient antenna. Dang me! I forgot to say "usually has the most directivity". There are antennas loaded with resistors and/or near the earth which I was not considering at the time.

Roy also wrote:
"Rhombics are typically 50% efficient, so more efficient antennas can have more gain while having less directivity than a rhombic."

True, and a reason we replaced a single rhombic with 3 curtain antennas, each covering a limited frequency range. This exchange was repeated many times. Broadcast power is precious indeed. The power formerly burned in a dissipation line was spread over a target area by a curtain antenna.

For point to point it is hard to justify replacing an effective, convenient, and low-cost antenna with three curtain antennas for a small power gain.

Let`s see. For triple diversity reception, we would need 9 curtains to replace 3 rhombics. For all the simultaneous program channels it`s 9x the number of channels for the number of curtains. We would need a lot of real estate because the TDR`s are a space diversity scheme. The rhombics had 10 wavelength spacings. The receive site rhombics worked like champions almost around the clock for years. Very few problems even when bad guys tried to make mischief.

> such an application. Comments?

Very important if it's elevated. The radials must show a low impedance
to function. If the radials were very mistuned, and say showed a high
impedance, it would nearly be as if they were not there. So you end up
running a whip, and your coax as the antenna. You don't want your coax
to be part of the antenna. So for a multiband antenna, you need
resonant radials for each band. At least one per band is the minimum.
But I don't consider one radial to be much of a ground plane. More of
a dipole with one leg sticking straight up..
> >
> > Also, if I used a vertical dipole instead, (like the Eagle DX) would

> is the effect of good ground versus lossy ground underneath such a
> vertical dipole?

It improves with the better ground. But only low 1/2 waves are
drastically effected. Once at least about 1/4 wave up, a 1/2 wave is
in fairly good shape as far as ground losses. Once a half wave up, it
quite efficient. But a ground mounted 1/2 wave is subject to losses
just like any other vertical. It's less than the 1/4 would show, but
it's still there. If you look at a commercial 1/2 wave on MW, they run

a system of 1/2 wave radials usually.

> Would "good" ground
> underneath actually impair this antenna for low angle radiation?

Would improve low angle performance.
>
> Now that my curiosity is piqued....picture this situation....7 MHz 1/4
> wave vertical antenna, 20 feet up with 3-4 radials. Below that set of
> radials, say 10 feet below, another set of 3-4 radials. Any advantage
> here by having the second set?

Depends on the band used, but overall, no. If you are running an elevated vertical, it doesn't make sense to waste radials at a lower height than the antenna. They are more effective per radial at the higher heights as the ground losses are less for one thing. Also, radials at lengths under the antenna could quite likely act as feedline decoupling radials, more than ground loss radials, although I guess in reality they would be doing both jobs. But those would usually be a 1/4 wave down, not 10 ft on 40m band. At 20 ft," just over 1/8 wave" your 4 radials will be equal to maybe 10 or so on a ground mount. Thats not going to be a barn burner...:(If you added the 4 radials at the antenna for 8 total, at least you are doubling to an appx 20 radial if ground mounted level. If you added them 10 ft below, on a 40m antenna , they would be fairly useless. At that length from the feedpoint on 40m, they won't really function very well at all.

Jeff wrote:
"What percentage of the total current do elevated radials really carry?"

That depends on their number, length, height above ground, etc. The aim is usually 100% of the displacement current which is nearly all the current fed to a radiator.

If you have an elevated dipole, you want nearly all displacement current to be between the halves of the dipole. In an unbalanced antenna, the displacement current is between the salient radiator and its ground return. A ground return may be a car body, counterpoise, ground-plane, earth radials, etc.

The earth is lossy, and if radials don`t succeed in intercepting the displacement current, it flows in the earth on its way to complete the antenna circuit. Skin effect determines penetration depth in the soil and this is a function of soil impedance. The higher the impedance, the deeper the current flows, Formulas are found in many texts, but current flow below the surface is undesirable if it replaces flow in a radial. Current flow is much less lossy in the radials. Broadcasters get almost 100% efficiency capturing displacement current with 120 radials of only 1/4-wavelength (as it would be in free-space). At the earth`s surface, 1/4-wave radials are actually significantly longer than 1/4-wave because the earth slows wave propagation.

Elevated radials capture displacement current because they are closer to the radiator and elevation makes them a more attractive target for capacitive flux. Elevated radials also tend to block access of the displacement current between earth and the radiator.

The space between earth surface radials probably gets as much or more direct displacement current, but this current has to travel only a short distance to a radial which carries most of the current due to its high conductance.

> with the portable AM receiver anywhere near that wire. My dipole
> is relatively unaffected by the noise.

If you can trace the noise to their equipment the FCC says they are supposed to fix it.

There is a noise here that comes and goes. It appears to be on all bands and my show up virtually any time day or night...although it's more often at night. The noise *might* be from a high tension transmission line about a half mile away. I say might as it really doesn't fit the profile. True it is a series of closely spaced pulses that are about S2 on 6-meters and S-6 on 20 meters tonight..er this morning. That is with the noise blanker off. With it on they don't show on 6 and run about S-2 on 20.

The noise tonight on 6-meters sounds almost like precipitation static, while 20 ismore of a rushing sound.

I may go a week and never hear any of the noise on 6. I don't hear it all that often on 20. Then I may hear it for 3 or 4 days in a row. I don't have any verticals here (at this site), except for 144 and 440.

Under normal circumstances, I can't think of a thing.

It's that otherwise in there<:-))
If for some reason the station ground should become disconnected, your
electrical system is now connected to the water system and under some
conditions put a healthy voltage onto the water lines. One guy was darn
near electrocuted in a small town NW of here when he disconnected the water
system which had the electrical system tied to it. In his case there was no
other ground. When he went to put the two connectors back together the
ground went right through him. Luck had it that he fell and broke contact.
>
However bearing thta in mind with a metal water system, there are supposed
to be *two* 8 foot ground rods, 6 feet apart, connected to the ground just
outside (on a 200 amp service). If the soil dries out the the water system
can become the sole ground. This is not bad as it's serving its purpose.
It's just a "potential" danger for the unsuspecting.

If the system electrical ground gets disconnected from the Earth, all your metal appliances, electric stove, metal outlet boxes, service box, computer, ham rig, and everything else having a three wire plug could be dangerous. So you could apply the same argument for not connecting them to ground that you can for not connecting the water pipes. Sorry, I don't think it's a good argument. I connect everything conductive in my house that I can to the system ground -- and make sure my Earth connection is up to code. If the code doesn't provide an adequate ground when the soil dries out, you should supplement it -- and bring it to the attention of your state's electrical board -- not start disconnecting things from the ground system in the hope that it'll reduce the danger.

>
At the feedpoint, where all the radials join, the answer is exactly 100%. The current in the vertical is exactly equal to the sum of all the currents in the radials - the vector sum, that is, because the radial currents are unlikely to be all exactly in phase. (If the feedline surface current is not adequately choked off, then the feedline becomes another unintended radial, and so that current adds to the total.)

That percentage summation of currents at the feedpoint is exact - and it's just about the only thing that does *not* change with radial configuration. What varies with the configuration of the radials is the effective *resistance* through which those radial currents flow to arrive back at the feedpoint... and therefore the total current.

In the ideal situation where the radials are very long and very densely packed, they completely shield the earth below. The field from the vertical induces currents in your lossless ground screen, but no field penetrates through it, so no currents are induced in the lossy dirt. In the practical situation, some of the field from the vertical 'leaks' between the radials and induces circulating currents in the earth. But electromagnetic induction always works in both directions - the circulating earth currents also induce currents back into the radials. This makes the radial currents different from what they would be if the earth wasn't there.

This two-way EM induction also means that the earth *resistance* is coupled back into the radials. It's as if each radial acts as the primary of a transformer, whose secondary is loaded with resistance. The radials themselves have next-to-zero resistance, but the coupling makes them behave as if they have resistive losses.

The overall effect of a lossy ground system is well known: less current flows (for the same driving EMF) so the feedpoint impedance rises. The ideal lower limit is the radiation resistance of the antenna; the extra ohms in a practical installation are the effects of the distributed earth losses.

All these interactions affect the overall behavior of the antenna: the total current, the feedpoint impedance, the shape and size of the current profiles on the vertical and on each radial, and the percentage of the RF energy lost in heating the dirt. Those are the things that change with radial configuration.

But the percentage of the total antenna current that the radials return to the feedpoint is always 100%.

a 1:9 or 1:16 balun that will step down the high impedance of a long
wire. Some say they need this some say it is not important at all.

Fixing all the power line noise in Madisonville, TX would bankrupt the
power company. There are hundreds of locations where the power line
noise drowns out the local AM station. Again, my horizontal dipole is
relatively immune to that noise. One of these days, I will rotate my
20m rotatable dipole into the vertical plane and measure the difference.

> transmission line won't even reach to the moon.

"Fred Hambrecht Sr." got it wrong
> And a 20 year one won't reach Alpha centuri

If the Vf was 100%, then a 20-year long cable would reach there and back 2.5 times. Alpha Centuri is about 4 light years distant.

If the Vf was 80%, then it would reach there and back only twice. If the Vf was very very close to 0%, then you could keep the cable in your pocket.

When a 'longwire' is an odd number of 1/4-wavelengths long its input impedance is very low. So the balun makes things worse.

It also makes the balun manufacturer and salesman very happy.

If the receiver does not have one built in, the money would be better spent on a pre-selector.

|> otherwise properly grounded, what's the harm in connecting the water
|> pipes (or any other metallic objects) to ground?
|
|Under normal circumstances, I can't think of a thing.
|
|It's that otherwise in there<:-))
|If for some reason the station ground should become disconnected, your
|electrical system is now connected to the water system and under some
|conditions put a healthy voltage onto the water lines. One guy was darn
|near electrocuted in a small town NW of here when he disconnected the water
|system which had the electrical system tied to it. In his case there was no
|other ground. When he went to put the two connectors back together the
|ground went right through him. Luck had it that he fell and broke contact.

The National Electrical Code (1981) states:

"250-80 Bonding of Piping Systems.

(a) Metal Water Piping. The interior metal water piping system shall
always be bonded to the service equipment enclosure, the grounded
conductor at the service, the grounding electrode where of sufficient
size, or to the one or more grounding electrodes used...."

In the case of the well, the code also requires a supplemental
grounding electrode to prevent the very occurrence you provide as an
example.

|>
|However bearing thta in mind with a metal water system, there are supposed
|to be *two* 8 foot ground rods, 6 feet apart, connected to the ground just
|outside (on a 200 amp service). If the soil dries out the the water system
|can become the sole ground. This is not bad as it's serving its purpose.
|It's just a "potential" danger for the unsuspecting.

The point of bonding and grounding is to have every metallic object that a person might contact be at the same potential as the earth he is standing on.

Approximately 1/2 to first order.

>Where is current at that they don't carry?
Is it in the ether between
>the radials or flowing
>along/through the ground below?

It is in the rest of the antenna, eaten up (to be a bit simplistic) as
radiation resistance or ohmic loss.

>Do the radials represent a low resistence to RF at a certain height
>and hence most of the RF takes
>the path of least resistance?

They represent a counterpoise. They most certainly radiate--but that radiation
typically cancels in the far field.

I had one years ago replacing a 2-el quad. I thought it performed well
but not overwhelmingly well. The broad bandwidth was nice for my solid
state rig.
As for price, I have no idea of the going prices these days but it seems
certainly worth $200. Expect to replace some of the plastic pieces...as
I recall, the earliest ones used some pieces that deteriorated quite
rapidly.

More important than the antenna is listening at the right time. I knew somebody who listened for DX every night. He never heard any, because it never comes in at night. Right now, until about the end of the year, there is a chance of F layer DX between about 8AM and noon local time toward the East and South; afternoons towards the West. Next summer, and also early January, sporadic E could happen any time of day. Sporadic E is usually good for 800 - 1200 miles. Very rarely as short as 500. You will work people for sure if you get on 6 during the January VHF contest. It runs from Saturday afternoon until Sunday night, usually the weekend before the Super Bowl. Check QST or the ARRL web site for date and time about a month from now. What you need for the contest is to know what your grid square is.

I used plastic egg insulators used for electric fenses.. They are cheap
and have parallel paths about an inch apart. I fixed the insulator to one
feedline wire with a short piece of 22 AWG that is soldered above and below
the insulator. The other feedline wire floats and is held tight by tension
at the end of the open wire feedline. My 480 ft loop and feedline is one
continous 600 ft length of harddrawn stranded copper.

Enjoy the benefits of open wire feedlines !!

You'll have to ask Einstein - that's his speciality ('Riding on a lightbeam' and all that). If I had to take a guess, I would say that the Vf would depend on your point of view (frame of reference). One might say that it is 'relative'.

2221. antenna resonance via grid dipper?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-09 20:23:43 UTC
From: carkenord@juno.com
Message-ID: <4346b55e.0211091223.42e9b3e@posting.google.com>
Source record: 131659

I have a military GDO...the AN/PRM-10. I also have a Millen 90651 dipper. I am somewhat familiar with the useage of these units.

I need to fine-tune (for resonance) a 20M meter delta loop antenna......desired resonance of 14.225 Mhz...and I want to do the fine tuning with the antenna in its final place _UP_ in the air. When the antenna is up in the air, I cannot access _ANY_ of it for "dipping".

I REALLY want to see the resonant freq of this antenna.

I understand that I can attach a 14.225 Mhz half-wave of 50 ohm coax to the antenna feedpoint, short the OTHER end of the coax with a small single turn loop, and couple the GDO to that loop, and tune the GDO for a dip.

Ok.....here is my question.......... Lets say that I don't have a piece of 50 ohm coax cut to a halfwave at 14.225 Mhz.

Lets say that I have some 50 ohm coax, and lets say that I have used the GDO to determine the "velocity factor" of that coax. I have also measured the physical length of this coax......it's NOT a half-wave, and its not a multiple of a half wave at 14.225 Mhz.

Is there some math, or better yet.......a simple computer program.....that would allow me to get the "TRUE" resonant freq of the delta using the piece of coax I just described?

In other words.......I hook the "non-half wave" of coax to the antenna, waaaay up in the air, and I couple to, and dip...... the other end of this coax. I take the "dip" freq, the velocity factor, and the physical lenghth.....and enter those 3 facts into a computer program.........the program tells me the "TRUE" resonant freq of the antenna.

Izzat possible? If yes.....where can I obtain the computer program......or the necessary math........?? URL's....?? Websites??

I know NOTHING of Smith charts.

Thank you...... Lee Carkenord KA0FPJ

Message-ID: <usqtvijg0b1i46@corp.supernews.com>
Source record: 131663

Now that I have read all sorts of stuff I thought the group might actually like to see some VSWR data:
I have double bazookas on 160, 80 and 40. They radiate as well as a dipole. I have built and compared both.
All three antennas are constructed with RG8X 1/2 wavelength long with the shield split and fed at the center.
The ends are shorted with wire added such that the coax resonance and the antenna resonance exactly coincide.
The "exactly coincide" is very important. I built several copies and bought an MFJ analyzer before I got it right.
Antenna heights vary from 30 feet above ground for the 40 meters to 50 feet or so on 160.

160 meters:
KHz VSWR
1800 1.5:1
1870 - 1940 1:1 70KHz of 1:1 SWR
1900 3:1

80 meters
KHz VSWR
3500 2.6:1
3700 2.0:1
3790 1.5:1
3870 - 3950 1:1 80 KHz of 1:1 SWR
4000 1.2:1

40 meters
KHz VSWR
7000 - 7300 1:1 300+ KHz of 1:1 SWR

These are measurements I made while sitting here typing this post.
If you don't believe me come measure 'em your self. ;^)

From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <aqk1obaor2@helle.btinternet.com>
Source record: 131664

May I suggest you don't want to know what the resonant frequency of the antenna is all by its lonesome self. It is never exactly what you expect it to be even if you can do the trick. Just erect the antenna to conform to the simple calculated dimensions or to the dimensions you are copying from somewhere or somebody else.

The really USEFULL thing you want to know is the resonant frequency of the WHOLE SYSTEM as seen when looking into the transmitter end of the feedline.

Assuming you have an S-meter, just sweep the transmitter over the frequency band, and more if you can manage it, and watch the S-meter.

Resonance occurs at the frequency where the S-meter has a reasonably sharp minimum value. It doesn't matter at all what the minimum SWR meter reading actually is. (There may be screams of anguish in the background!)

Having found what the resonant frequency is you can mess about with things until it's in the part of the band you are interested in. Then try messing about until the SWR reading is what you would like to see.

Always include changing the length of the feedline with the messing about.

Try not to be disappointed if you can't get it down to 1-to-1 without a tuner. Nobody else ever manages that anyway.

(Antenna tuning with a dip-oscillator is seldom successful, firstly because of the difficulty of coupling the oscillator to a low-Q antenna and secondly because the coupling arrangements inevitably de-tune the thing you are trying to tune. It's the cursed laws of nature. The ideal instrument is one of these new-fangled, hand-held, antenna analysers before the battery goes flat. Even then you have to climb the mast which worries the XYL and the kids.)

Obtain some 5/16" wood dowels. Dry them thoroughly and then soak them in hot candle fat. Or just in ship's clear varnish.

There's not much point in cutting them longer than 1" or 2". They don't catch the wind so much. Use 16 or 14 gauge anamelled wire for very low loss. The Zo impedance matters very little.

>it improve shortwave reception?

Look on the back of your shortwave receiver. If you have a low impedance antenna connnection (usually a coax connector), and a high impedance connector (a terminal where you can stick a piece of wire), you are ready to go. Attach your long wire antenna (which may have a high impedance) to your high impedance connector.

If you have only a coax connector, you may or may not need the balun. Supposedly, the balun would transform the high impedance of the long wire to the low impedance of the coax connection.

So, what's on the back of your radio? We can give you better advice, knowing that.

Fellah by the call of w7fg, http://www.w7fg.com sells open wire feedline. You might go look at it, at his site. Maybe he will sell you just the insulators. Maybe you'd find it more efficient to just buy his feedline.

Otherwise, a length of pvc pipe, with a hack saw and an electric drill, should do you well... :-)

Egads Lee, why go to all that trouble? Feed it with ladder-line and
trim the ladder-line back at the transmitter until you find resonance
at your desired frequency using your GDO. With this feedline method,
the exact length of the loop doesn't matter. Put it up in the air and
forget it.

I am not too far from Ken and have another such Telrex. It is on the ground, assembled, and on saw-horses. The rear two elements do not have traps. They are 20 meter and 15 meter reflectors. Those two elements broke in the middle (in a LOT of wind). I have the pieces. If you buy Ken's antennas, consider buying my antenna too. You could then have two working antennas and a lot of high quality parts. (Or three antennas, one without 15 meters)
The beam is a real good performer. I worked a lot of DX with it.

If you were riding along with it, you would measure the same velocity factor regardless of your speed relative to everything else. If you weren't, you'd have
to adjust things so that both you and the coax measured the speed of light as being the same. See any elementary physics text.

I am getting well-intended responses to my question.....and I
really do appreciate the fact that people are taking the time to
respond.

However, my original question, precisely as I stated it, still stands.

I'm not looking for _OTHER_ ways to establish what the resonant freq
is.....I'm looking for a way to do it with my GDO, by dipping at the
end of a non-half wave of coax.

Now.....the thought also occured to me.....maybe what I want to do
is not possible? If that's the case, please....someone tell me that,
also.

Thanks again, folks.....I appreciate your help.

Why don't you set your transceiver on 20M, transmit a low power CW signal with your SWR meter engaged, and tune your vfo across the band? Where the SWR is lowest, wouldn't that be where the antenna system is more or less resonant?

when you dip your antenna while it is connected thru a transmission line of unknown electrical length you are dipping on the resonance of the system, antenna and transmission line...
you can't cut the transmission line to resonance because you don't know the resonant freq of the antenna...
so as suggested you can use your xcvr at low power to plot swr...
be aware that if you change the length of the transmission line the curve will shift..
you need to determine the reactance and for that you need a noise bridge or better still the MFJ antenna analyzer if you really want to know the facts..
if you can find a copy of QST April 1977 page 40 thru 42, gives a good explanation...
good luck
hank wd5jfr

2254. DIpole mounting question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-10 16:31:21 UTC
From: Mike M <nospam@nospam.com>
Message-ID: <FD2CFD3C0F7EC3F0.344085C68AB7705C.B818F74DAE0C4896@lp.airnews.net>
Source record: 131593

I'm thinking about antennas now that I've decided to get my General.
Should be next month.

I live in a fairly restricted suburban neighborhood. I'm sure I could
get away with a conservative antenna like one of the Force 12 vertical
dipoles of maybe some other vertical. But in looking around and reading
the dipole looks a heck of a lot cheaper and performance wise a good
start.

Question is can I mount this under the eaves of my house without any
significant degredation in performance? I have a perfect 70 ft. run if I
can get away with doing this. How about over the roof? I can camouflage
these very well. I know in a perfect world that away from the house is
ideal but I can't get away with that.

Any ideas?

2255. Re: DIpole mounting question

Newsgroup: rec.radio.amateur.antenna

Source record: 131594

Mike,
Sure, you can get away with it, sort of. I think
you realize that an antenna mounted under the eaves
isn't going to be the 'best' in the world, right? You
also need to think about the problems that can crop up
by having an antenna on, or very close to your house.
The 'biggy' will be interference with other electronics
in the house. If you're lucky enough not to have any
RFI, then I think the dipole would be an improvement
over a vertical (in most cases).
'Doc

2256. Re: antenna resonance via grid dipper?

Source record: 131597

The fundamental problem you have in trying to make your measurement is that you don't get enough information with the GDO, and it's not useful information. If you knew the impedance (magnitude and phase, or resistance and reactance) at the input end of the line, and the electrical length (length times velocity factor) and loss of the line, you could find the impedance at the far end, and by varying the frequency, find the frequency at which the antenna itself is resonant. If all you know is the resonant frequency at the input end of the line, you can't even determine what the antenna's impedance is at that frequency. To do that, you'd also need to know the resistance at the input end at resonance (and the line electrical length and loss). But even if you knew the antenna's impedance at the frequency where the line input is resonant, you still can't use that information to find where the antenna would be resonant unless you know something about how the antenna's impedance changes with frequency.

So the answer to your original question is no. You can't.

I build one TA33 jr 20 yrs ago and I only have the commercial brochure which tells that the boom length is 12 ft long, max element length is 26ft 8in (reflector), and turning radius is 14ft 9in. There was also a TA31 whose element length was 24ft & 7 1/2 in long (it was possible to upgrade it to TA32 or TA33 with the same driven element). Following the brochure the normal TA33 (not the junior) had a max element length of 29ft and a turning radius of 16ft and a boom length of 18ft. I also have a separate sheet telling that the driven element of my antenna was 24ft & 8 1/2 in (why mine ?). There is also a reprint of the RSGB bulletin May 1960 (by E. Mosley W0FQY) on how these traps are working.

I am not sure it will help you to make a copy but it's all I have.

Hi Lee,

Just flew through your neck of the woods last night (I play around the
Springs area and Cripple Creek - Victor) back to "dry-weather"
Seattle.

You already know the solution as you sheepishly offered earlier
>>I know NOTHING of Smith charts.
Well, this is the best opportunity to start (no point in fumbling
around with it on paper if you have nothing to appreciated by). Your
situation and question are a classic example of Smith chart
application.

Hi Richard,

The logic of your last statement has the conclusion negating the
premise. How is it that same inch or centimeter does not have the
dimension status of a yard or meter?

This sounds like: it takes more than one unit to make up one
dimension.

Consult NIST:
http://physics.nist.gov/

I'd very much have to agree here - I have had very good contacts from Oz to Japan and Hawaii during the right times using a modified 11m vertical and only 10W. When conditions are right, a wet piece of string will work!!

I also agree that for SSB a beam would be ideal, but some of us aren't able to achieve the ideal setup!!

Hi Roy,

Part of the original post was:

| I REALLY want to see the resonant freq of this antenna

So I'm surprised by your reply:

| So the answer to your original question is no. You can't.

You are true about the context (magnitude, phase, resistance, reactance, etc) but I'm quite surprised about the resonance. I have cross-checked different books and this are the warnings about measuring resonant frequency of antennas:

1. ARRL handbook 1973 - p.521 - "Caution must be used in checking transmission lines or antennas - and, especially, combinations of antenna and line - on this account, because these linear circuits have well-defined series of harmonic responses, based on the lowest resonant frequency, which may lead to false conclusions respecting the behaviour of the system".

2. ARRL handbook 2001 - p.26-17 - No restriction about mesuring the resonant frequency of an antenna, just "Battery-operated are convenient for antenna measurements".

3. A. Raffin F3AV - L'émission et la réception d'amateur 1952 - p.375 - (I translate) "When the antenna resonates this absorption is shown on the 6AF7 indicator. You'll couple it loosely for having more accuracy. In reading the variable capacitor curves, you immediately see the resonant frequency of the aerial...."

4. Radio designer's handbook - F. Langford-Smith 1957 - p 1325 - He basically uses a valve voltmeter and a signal generator for measuring the primary resonant frequency of aerial and rf coils, which is not very different (gives a sharp increase instead of a dip) than using a GDO.

5. Les Antennes - Robert Piat F3XY - 1965 - p.227 - (I translate) "We can control the resonant frequency of an antenna with a GDO. this measurement will permit to estimate the selectivity of the antenna ... This equipment will permit to detect the parasitic resanances."

6. Practical antenna handbook - Joseph J. Carr - 1994 - p 465-467 - One of the most common instrument for determining the resonant frequency of antenna is the so-called "dip oscillator", or "dip meter"..... etc.

So Roy, maybe we don't speak about the same things but I think we can do it and I experienced measuring antenna resonant frequency with a GDO. If I am wrong, tell me where and why. Thanks

73 de ON5MJ - Jacques.

Ken

I would suggest a Dir. Coupler with about a 20 dB sample. This should work great with the counter and not cause any problems in the feedline.

2270. Re: antenna resonance via grid dipper?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-11 01:17:41 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <usu4q3bkkbod4@corp.supernews.com>
Source record: 131612

The problem is one of definition. When someone says the "resonant frequency of the antenna", I take it to mean the resonant frequency of the antenna, as measured at the antenna feedpoint, with no transmission line attached. The "resonant frequency of the system" is, to me, the resonant frequency as measured at the input to the transmission line. Only if the transmission line is a multiple of an electrical half wavelength long, or the antenna's resistance at resonance equals the line's impedance, will the two resonant frequencies be the same. I interpreted the question to be: "If I measure the resonant frequency of the *system*, can I use that information to determine the resonant frequency of the *antenna*, if the length of the feedline isn't a multiple of a half wavelength (and assuming I do know the electrical length of the line)?" The answer to that question is no.

Let me give you an example. I used the 15MQuad example file from EZNEC. This antenna is resonant at 21.15 MHz, where its feedpoint resistance is 112.6 ohms. The question, as I understood it, was whether this frequency of 21.15 MHz could be determined with a GDO connected at the input end of a cable. I arbitrarily chose a 50 ohm cable with length of 15 meters and velocity factor of 0.66. (It wasn't entirely arbitrary -- I made sure it wasn't too close to a half wavelength at 21.15 MHz.) At 21.15 MHz, the frequency at which the antenna is resonant, the impedance at the input end of the line is 45.2 - j39.4 ohms, not at all resonant. Here's what you'd see with a GDO at the input end of the cable. There would be a "sort of" resonance at 20.96 MHz. It's not a true resonance -- the amount of reactance drops as frequency increases, then increases again, without going through zero. So you might see a shallow dip on the GDO. The impedance at the input end of the line at 20.96 MHz is 38.6 - j32.5 ohms, still pretty reactive, but that's as low as it goes in that region. At that frequency, the antenna's feedpoint impedance is 91.74 - j32.69 ohms, definitely not resonant. With the GDO, you'd find a true resonance at 23.33 MHz. At that frequency, the line's input resistance is 7 ohms, and the antenna feedpoint impedance is 209 + j172. And you'd see a parallel resonance at 19.45 MHz, where the line's input R is about 1400 ohms and the antenna feedpoint Z is 68 - j303.

Now, from knowing the resonances of 19.45 and 23.33 MHz, or the reactance dip at 20.96 MHz, could you determine that the antenna is resonant at 21.15 MHz? No. Can you measure the resonant frequency of the system? Yes. With a GDO, you'll find there are resonances at 19.45 and 23.33 MHz. But what good would it do you to know those frequencies, where the resistances (which you wouldn't know) are 1400 and 7 ohms respectively?

2271. Which Scenario is Least Likely to be a Magnet for Lightning?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-11 01:26:58 UTC
From: Gary Brown <gbrown@nc.rr.com>
Message-ID: <CHDz9.94980$dn3.3522005@twister.southeast.rr.com>
Source record: 131609

Antenna:

Stealthy 78-foot 5-band W9INN Dipole with W2AU Ansulator center insulator.

Twenty feet high, in clump of pines and oaks about 50' tall on residential quarter-acre lot

Feedline is 80' of Belden 8214 RG/8. Coax enters house via drilled board wedged in window sash opening of second-story shack.

Scenario 1

Coax is always connected to SPDT switch that is connected to station ground. Center position of switch disconnects center conductor from station when not in use. Station ground is 6-foot rod in ground , directly below shack.

Scenario 2

Coax is always disconnected when station is not in use, and PL-259 is left lying on wooden shelf. Coax is not connected to any grounding.

Second antenna is a 50-foot high sloping inverted L fed from a wall-mounted Icom AH-4 coupler. It was sling-shoted over the top of a tree. This antenna is always disconnected from station via a knife switch when not in use. Far end of antenna is connected to another ground rod at base of tree via a 1-megohm resistor.

Located in rather lightning-prone central North Carolina.

Comments?

Alas,

Even if it is resonant as per Cam's post, it can still present a non-50 Ohms load to the transmitter, requiring a "antenna tuner".

It seems you have found a suitable solution by adding more turns of
wire. You could also trim back to one turn and slip that turn between
cover or panel to pick up the RF within the case (provided it is a
simple oscillator drive and not a synthesized one with RF soup inside
the rig). Experiment with this loop sniffer and perhaps move it into
the guts of the oscillator (you want a small single turn loop so as to
not "pull" or load the oscillator). If this works, you can add a
panel mount test jack and hardwire the loop to it. If it works once,
it will work forever.

>
>Ken KC2JDY

Hi Ken,

500 Ohms does provide a considerable SWR (as does the suggestion to snip the pin on the connector to isolate the meter more) - as it should. You want to reflect as much power as possible on that test port (as distinct from reflecting power from an in-line port which means trouble). The SWR (at that port) simply serves as an open switch (a leaky one) removing the meter from the bulk of the power. If you were to add a 1 Ohm resistor across the meter input, the power applied to the meter would plunge further and probably still provide adequate signal for your purpose.

I will leave the math to you, you are moving in the right direction.

Hi OM,

Others have affirmed that the hammer will come down if caught
(especially at those elevated power levels of 5W).

One interesting tidbit, merely alluded to, is that Amateur Radio
service is the only licensed service that allows non-type accepted
equipment. With our license we are uniquely privileged to design and
modify our equipment without going through cumbersome and costly type
acceptance testing and reports. It is also our responsibility to
insure that we do not interfere, nor to exceed emission levels in
harmonic or adjacent frequencies.

Too bad so little time is put to exercising this right. The term
breadboard seems to be fading from the designer's language (being
shouldered out by the term prototype which itself is in the dodo
class) and is further removed from its original application as a
literal description for a primitive transmitter.

Also too bad is that the FCC does not allow us to operate anything but
communication gear (no broadcasting and no transmissions without the
intent to communicate). I would love to build and operate Amateur
Broadcast Band (AM). The FCC need simply mandate AM receivers cover
that spectrum in the 160M band and allow us to transmit (conforming to
non-commercial activity) what we think is entertaining to no one in
particular (and with no appeal for "owning" a frequency). Extend that
one to allowing an Amateur Broadcast Network (thus allowing
controlled, non-interfering operation in regions).

I would also love to build an Amateur Radar and make my own HAARP
measurements. I ponder the implications of a Ham Mobile Maser in a
traffic snarl.... Legal Limit pulse of course.

Gary,
I'd have to say that the likelyhood of a lightning
strike in case #1 is approximately 50%. On the other
hand, I also have to say that the likelyhood of a
lightning strike in case #2 is also approximately 50%.
Since you asked for the 'least' likely scenario, place
a negative sign (-) in front of both probablility figures.
That yields a -100% probability of a lightning strike.

Thank you Roy for this important explanation - to me certainly - ,

I effectively have not yet used EZNEC (the basic free version is downloaded but not yet used, just have begun to read the explanation, hmm.. I promise I will do soon because I don't want to pass away without mastering this kind of tool) or similar program, so I never realised that the system could have different resonances than the radiating element alone when the transmission line length is not a multiple of lambda/2 or doesn't have the same Zc than the Zo of the antenna. It seems thus that erroneous statements were and are still printed - including in reference books, leading readers to erroneous practice because of lack of warning - about the use of a GDO connected to the entry of a system composed by an antenna and a random transmission line.

The first conclusion is already stated: I must learn more about the use of NEC.

The second one is about the use of tools like MFJ or Autek. It definitely seems that they provide a correct answer to the original question instead of a GDO. I have a small preference for Autek below 30 Mhz as they also measure the sign of the reactance and not only the size. Does somebody compare both equipment ?

Take a look at my no-tuner all-band dipole on my web page.
I use it on all HF bands without a tuner and my maximum
SWR is 1.6:1 That's why I say throw your loop into the air,
feed it with ladder-line, and perform the matching function
at the transmitter end where it is warm in the winter and
cool in the summer.

Gary, I grew up in south-eastern NC and the biggest lightning magnet seems to be the pine trees! If your antenna is in their midst its prone to pick up some whopping surges. I'd say leave things disconnected when not in use. The only guys I ever knew that got zapped were the ones who depended on gimmicks and ineffective grounds.
In my area (Sandhills) it wasn't uncommon for CP&L to put down up to 100 feet of ground rod to get a decent ground at a utility pole and I've seen places where you could push an 8 foot rod into the ground by hand. So its very hard to depend on the earth as part of a good grounding system.
Don't forget to disconnect any rotor cables! Use a Jones plug or some other type of multi-pin connector for that.

-Bill M

2280. snake antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-11 13:05:19 UTC
From: rckchp@comcast.net
Message-ID: <6dc33f40.0211110505.2ce960b4@posting.google.com>
Source record: 131519

Yesterday (11/10/02)I was listening on 12m and I heard two hams discussing the "snake antenna". The ham who was advocating the "snake" said it consists of 136 feet of any type coax, with the braid and center conductor shorted (soldered together) at the far end and the braid opened, just the center conductor soldered at the pl-259 connector which connects to the xmitter. The coax is just laid on the ground, not necessairly in a straight line (thus the name "snake"). He claimed it works on all bands from 160m to 6m. He did not claim it was a really good antenna on 160 (the discussion was mostly about how to get on 160) but that it did work and was better than no 160m antenna.

Having a newly aquired spool of RG8X and no room for a conventional 160 antenna,I immediately had to try it. I attempted to break in to an ongoing 160 ssb qso, and while they acknowledged that there "was someone there" the noise level (thunderstorms in their area) was too much for them to get good copy. The fact that I was only using 10 watts (K2) probably didn't help, but I'll keep trying.

Has anyone used this antenna? What results? Thanks.

Rich K2CPE

Rich,
The 'Snake' antenna idea has been around for a while. What
the guys talking about it didn't say was that it's a receiving
only, antenna. It's usually at least one wave length long and
terminated in a resistor the same value as the coax's impedance,
(50 or 75 ohms). As you said, it isn't a really 'good' antenna
but it does work and is fairly 'quiet'. There was an article
about it in QST a number of years ago, I think, one of the
magazines anyway. I'm really suprized that anyone would have
heard you using your antenna on 160 meters...

You might like to take a look at the tri-band dish feed for 2, 3 and 5G, the so called paddle. There was something about it in QST a while back or check the W1GHZ web site. Although the frequencies are a bit different, the concept could point you in the right direction (pun intended). Some experimentation on 1.2 & 902, using PC board dual band antennas was inconclusive. Lots of variation due to the substrate propagation characteristics!

Hi:
The snake antenna is supposed to be a alternative to the beverage receive antenna on 160/80m. In ON4UN low band dxing book he describes it as a very poor substitute for a beverage antenna. It was never intended for transmitting and was not intended for use above 40M. Mostly its a very long dummy load with a very poor SWR.
If your interested, I would recommend that you get a copy of ON4UN's book. It has a world of information on antennas for the lower HF bands. I think you can get it from the ARRLs book store on the web.

>a true resonance at 23.33 MHz.
[...]

That begs a whole bunch of other questions about the way a GDO works -
or doesn't.

We've probably all read how a GDO is supposed to behave when coupled to
a simple parallel tuned circuit... but what about the more complicated
cases, like the one above? Why does a GDO behave the way it does? What
are the reasons behind a "sort of" resonance, a "shallow dip" and a
"true" resonance?

Has anyone ever published a real in-depth analysis?

Ralph Mowery wrote:
"I might have to look it up but I only calculate about 1400 miles not counting the velocity factor :-) "

That`s close enough.

The wavelength = 186,000 mi/sec / 60 Hz
That`s about 3100 miles. Half is 1550 mi.
Shorten the distance for velocity slowed by the wire and its environment, and Ralph`s diatance is about right.

1400 miles is an impractical transmission distance. About 1 KV per mile is needeed for efficiency.1.4 million volts is too hard to insulate, even using d-c.

Best regards, Richard Harrison, KB5WZI

Jacques,

The TA33JR is has a shorter boom, and shorter elements than a TA33. Actually, he does not need the dimensions. The tubing is predrilled. The furthest out holes are for CW, and the closest in are for phone. There may also be a set of intermediate holes for a compromise. Each of the 3 elements is color coded. The only question is as to which is the director end and which is the reflector end of the boom. I suggest looking at a picture at the Mosley web site http://www.mosley-electronics.com/

This website should be what you are talking about, at
least it is the same diagram.
http://www.kc7nod.20m.com/snake.htm

Try doing a search on google.com and you will find
several articles.

The snake does a respectable job of low noise receiving
and a pre-amp sure makes it better. Also you don't have
to waste dollars on expensive coax, cheap tv twinlead will
do the same thing (actually all you have is a folded
antenna and even a single long wire on the ground will
work). For matching just use a homebrew L-match or
a parallel-network depending on the impedance.. It
works very well if it is close to a wavelength long at the
lowest expected receiving frequency.

2290. SWR meter as watt meter

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-11 16:30:18 UTC
From: cprstn54zz@att.net
Message-ID: <3dcfd597.102136828@news-server.optonline.net>
Source record: 131529

For reasons of XYL appeasement, I am trying not to buy or make a QRP wattmeter.

My cheapo Radio Shack 21-525 SWR/Field Strength meter seems to reproducibly measure power on its "percent reflected" non-linear scale. (I.e. 50 watts shows as "25", whereas 10 watts shows as "5".)

By reversing the cables, I get full scale deflection with a 3 watt QRP radio with the sensitivity almost maxed out. It would appear that I could read down to 250 mWatts with this scale, plus or minus 50 mWatts -- which is good enough for my purposes.

Anyone else doing this with OK results?

Source record: 131530

I think it's not related to the behaviour of the GDO itself but to the frequency response of the whole system (antenna + line), each component having a different behaviour vs frequency, so the total behaviour is what Roy told. We have to investigate each component and the group.

I also guess if we replace the GDO by a signal generator and a voltmeter we will have the same results.

Am I right Roy ?

Looks like the Dipole strung out under the eaves of the house may be out. Too much hassle and risk of ladder accidents. Can't affort a vertical or one of the Force 12's vertical dipoles at this time either. I've been reading about Hamsticks used in the dipole config. with their dipole mounting kit. One guy on HAMNET says he uses dual 40's with an antenna tuner with great results on all bands. Boy the price on these sure looks right.

Is anyone on here using one?

Hi Ian,

The meter of a vacuum tube GDO measures the bias current flowing through the grid (generally discouraged in amplifiers) that comes as a consequence of positive potentials sustained in the attached, resonant tank circuit. The circuit operates in a clamping manner. When that resonant tank circuit is exposed to a load, that load robs the circuit of some of its power thus depressing the positive swings and current through the grid falls.

The complication is found in the nature of the load. A resistive load would uniformly rob power across the spectrum. A complex load will exhibit less than uniform characteristics. The GDO is a miniature Beachcombing Metal Detector with a VFO. You could also explore the difference between diamagnetic and magnetic characteristics exhibited by steel and brass. The only thing complicated about a GDO is keeping its output high and flat across frequency (done the old fashion way: manually twist a knob or exchange a coil to compensate).

Care should be taken to not mis-interpret a loading of the oscillator with the pulling of the oscillator (don't overcouple indiscriminately).

The instrument is quite simple, and for that reason a great deal of deduction may be applied to its presentation of results obtained in different scenarios.

Hi Rich,

The other posters are somewhat aghast at the transmit application -
and for good reason. However, this service is not unknown and falls
into a class of operation known as NVI (or somesuch alphabet soup)
that denotes Near Vertical Incidence (or peak lobe) characteristic.

This was used in the desert the last time 'round with Iraq for local
communication. The Desert Storm version gave the appearance of a
capital H built in the form of two dipoles paralleled. This is all
rather a vague description due to my only using it once for a field
day years ago. But suffice it to say that there is a class of
antennas built on the ground, in the ground, and under water.

This sucker will exhibit gobs of loss warming the daisies, but if you
can pay the cost, you couldn't find a simpler antenna.

Hi Ken,

What you describe is a good general low power indicator. It is best to leave it at that. Adding numbers is suitable for "logging" the reading only, not for quantifying power, voltage, or current. The reason is, that at low powers there is not enough potential in the power available to the detector to keep it out of its non-linear region.

If you can obtain a reliable power meter to operate in series with yours; then you may calibrate your scale and apply those to your logged readings. In all honesty you need know only two points: the actual value for a full scale deflection, and the actual value for a midscale deflection. In this non-linear region that is bound to be far off the expected 50% mark. The solution to many problems comes in simply observing the relationship of the needle to these two cardinal points.

In the case of a half-sloper, the coax "comes off the tower" somewhere near the top of the tower. With a crankup tower, the coax drop is outside the tower. This somewhat unusual combination was the basis for my question. (The question was "Should I ground the coax shield at the bottom of the tower? It would then be radiation element parallel to the tower, I assume.)

Hi Ken, you are doing essentially the same thing as a Bird wattmeter
does when one uses a different slug for forward and reverse power.
It works just fine.

Great compared to what? The efficiency of such an antenna
on 40m is in the ballpark of 8%. Put 100 watts into it for
30 seconds and then feel the top of the coil but be careful
when you do it. It's like grabbing a dummy load.

Richard, you are correct about NVIS antennas, and they
do work. If those H-dipoles were around 10 feet in the
air and had reflector/counterpoise wires laying on the
ground, then 40 thru 160 meters they are real players.
Of course a horizontal loop or a simple dipole with a
counterpoise on the ground will do the same thing.

Trouble with using a snake antenna for transmitting is
that it's really a floating no ground antenna. So without the
services of a ground lead (which I will not use) or
counterpoise it is probably at best a worm warmer or a
long dummy load. I would venture to say that a regular
dipole laying on the ground would be a better xmt/rcv
antenna if there was no other option.

The snake antenna is great for DXing on the Top Band
and there are lots of folks that use them on the upper
bands on Receive only.

Source record: 131540

Hi Bill:

We are talking about two different things. But, connecting the shield of the coax to the tower in more than one place will not change the performance of a sloper. In a sloper the tower is the other half of the antenna. ON4UN in his "Low band DXing" book makes the claim that in a sloper, the tower does most of the radiating. Something like a top feed grounded vertical and the wire acts as a single elevated radial.
I don't know if that is true, but for lighting protection, connecting the shield of the coax at the point the coax leaves the tower is common practice.
ON4UN's book is full of very useful information and I think is a must read for hams interested in antennas for the lower ham bands.

Mike,
That's a fairly common thing to do, and there's
been a lot of people try it. They usually don't
keep it too long though. Using two 'Hamsticks' will
work as a dipole for the band it's made for. Using
it on other bands isn't going to work too well at
all. A dipole made like that is going to have a very
narrow 2:1 bandwidth, you won't 'move' frequency
far with out a tuner. It does work though...
'Doc

2306. Re: antenna resonance via grid dipper?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-11 22:35:07 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <ut0fla660fk2c1@corp.supernews.com>
Source record: 131545

With a signal generator and voltmeter, you can find the magnitude of the impedance at the cable input. That's more information than you get from a GDO, but still not enough to determine where the antenna is resonant. With the impedance magnitude and a Smith chart or computer program, you might be able to make some guesses, though, since you've now reduced the number of possible frequencies. And with a handful of capacitors and/or inductors of known value to put in series with the generator to make additional measurements, you could find the frequency you're looking for.

One caution, though. Any time you're trying to determine an antenna's impedance by looking into a transmission line, you have to be very aware of the effect of cable loss, even if you're using a multiple of a half wavelength. The effect is the least if the cable's impedance is close to the impedance you're measuring. But if the cable's impedance is quite different from the antenna impedance, even just a little loss will cause a surprisingly large measurement error. The effect of loss is to skew the input impedance toward the characteristic impedance of the cable, which is why you'll have the least problem if the cable is approximately matched to the load. You can still make reasonably accurate measurements if you do the imedance transformation with a program capable of doing lossy-line calculations and if you know the line's loss. But as the loss gets higher, accuracy suffers as you get more and more isolated from the antenna by the line's loss. That is, large changes in the antenna impedance cause smaller changes at the input as the line gets lossier, so small measurement errors translate into large errors in antenna impedance.

Of course, the presence of common mode currents on the feedline is another whole problem.

Occasionally I get a query from someone wondering why his measurements of antenna impedance don't match EZNEC's predictions. Investigation often shows the reason to be that the measurements aren't very good. Few people appreciate just how difficult it can be to make even moderately accurate measurements of antenna impedance, let alone such things as gain and pattern. It's fortunate that we can so often get by without really knowing what the impedance, gain, or pattern of our antennas really are.

Source record: 131542

Yes, his book is one of those that states that coax should *always* be run inside the tower. Unfortunately, this overlooks the large number of crankup towers that are used. Perhaps he is a little too dogmatic in some statements.

If I ground all the coax at the bottom of the tower, this increases the number of connectors involved (and each has loss(?) and is a point of failure.):

Quad (top of tower)
quad element to coax switch (on top of tower) one connector (+
actual loop connection)
coax switch to bottom of tower two connectors
bottom of tower to lightening protection two connectors
lightning protection to coax switch at rig two connectors
coax switch to amp two
connectors
amp to rig two
connectors

Half sloper: same, excluding the coax switch on the tower.

At the moment, I do not have any lightning protection, so I have two fewer connectors than listed here. For someone who *hates* installing these connectors, this is too many.

Regards,

Bill
W2WO

If you're into building your own, I have a design you might like.
It's inexpensive to make, not bulky, and trapless.

From: carkenord@juno.com
Message-ID: <4346b55e.0211111641.779500ed@posting.google.com>
Source record: 131549

I can build a 2 element "delta-loop" antenna......(each element an equilateral triangle.)

This would be for 15 meter ssb.

I live in Colorado, and this antenna will be for dx'ing.

I can make this antenna with the apex up, fed at the middle of the base/bottom.

Or, I can make it apex down, fed at the apex.

In either case, apex up or down, the feedpoint will be about 15 feet above ground....feeding with 50 ohm coax.

Which configuration would be better for dx'ing from Colorado?

Thank you..... Lee Carkenord KA0FPJ

If you have any trees in the yard, try a wire vertical supported with a
piece of PVC. I've built 10/15/20m verticals this way (its a W6SAI design)
that use rotator cable cut to quarter wave as elevated verticals. Camouflage
paint the PVC and it will work very well.

Good luck and Good DX.

Bill, W4WNT

Yes, elevated radials work well and you don't need as many of them. 4-6
elevated radials made as you describe should work well. You can also make a
wire vertical supported by PVC pipe (triband works). Much cheaper!

Good luck and Good DX.

2314. Re: antenna resonance via grid dipper?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-12 02:00:25 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <ut0rmagehsb86a@corp.supernews.com>
Source record: 131553

From your description of the operation, it sounds like the depth of the dip would depend primarily on the magnitude of the impedance across the coupling loop. If so, the "sort of" resonance at 20.96 MHz in my example would give a shallow dip, the resonance at 23.33 MHz would give a deep dip, and the parallel resonance at 19.45 MHz would cause the meter indication to peak rather than dip. Which would be interesting to watch, but providing no useful information for the problem at hand that I can see.

The only "GDO" I've ever owned is a Heathkit "Tunnel Dipper". It was flaky at best -- the output changed level across the band, it would stop oscillating altogether if too heavily loaded, and was generally unreliable. So my experience is very limited.

Hello Mike,

I'm using a 20 meter dipole made from 2 Hamsticks.

It's up only ~ 12 feet and is getting out quite well.

I routinely work into Europe on cw using a FT-817 at the 2.5 watt setting.
Have also worked some into Africa, South America and Russia.

This started out as a project for a portable and vacation operation type of
antenna and has worked out well enough that I have left it up and use it
most of the time.

I'll be interested in hearing more about using a 40 meter version for
multiband operation.

Hi Roy, as you know, I vary the length of my ladder-line to achieve
a tunerless match to my transmitter. If I know the length of the
ladder-line, its Z0, and its VF, then using a Smith Chart, I can
get a very close approximation to the antenna feedpoint impedance
by first finding a current maximum point on the ladder-line.

Both will suck ass for dxing, since your 15m antenna is only 15 feet above ground. If you could raise it any higher, then things would start to matter. The least what you can do is make it apex down, since then one of the triangle sides is as far as possible from the ground.

Don't bother making it a multi-element beam at this height because it will never work any better than a single element.

Height to antennas is what location is to real estate.

2322. K9AY Matching Transformer Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-12 05:40:16 UTC
From: Jim <jbollit@ix.netcom.com>
Message-ID: <aqq47srif1@slb6.atl.mindspring.net>
Source record: 131561

I set up a single loop K9AY to use as a low noise antenna to phase with.

I wound an impedance matching transformer with a 9:1 ratio.

I wound the primary on a Mag inc W material core using 15 turns and wound a separate secondary of 5 turns. I connected the coax to the 5 turn winding and one end of the 15 turn winding to the end of the K9AY and the other end to a ground stake. I tried the antenna and noticed that signal level were significantly down to what I expected. I then wound an autotransformer type of matching transformer with 15 turns of wire with the coax tap 5 turns up from the ground connection. The signal levels were 20 dB higher than with the isolated transformer.

I want to use an isolated transformer for noise purposes, but the signal level is to low.

Any help appreciated.

Jim

No connectors are needed.
They recomend stripping the jacket back and grounding the braind right to
the tower and then grounding the tower. They recommend against inserting
connections, but that can make sealing the cable a bit more complicated.
Check the PolyPhaser site.

I use two slopers on 75 and 1 on 40. All coax runs on the outside of the
tower. The tower in this case has little to do with the radiation. I use
half wave center fed dipoles at close to a 45 degree angle.

Portland's forcast, from the _Oregonian_, Nov. 11:

"Breezy Monday with more clouds than sun as well as a few showers. High 56. Windy and mild Monday night with periods of rain, some of the rain will be heavy at times. Low 49. Windy Tuesday with rain tapering to showers. High 58. Clouds and sun Wednesday; a stray shower. High 56."

Y'see, in a "wet" winter, the rain wouldn't taper to showers, and there wouldn't be any sun on Wednesday.

The 5-day forecast shows the weather getting back to rain on Thursday and Friday. You can see 'em lining up out there in the Pacific at http://www.ssec.wisc.edu/data/west/latest_westir.jpg.

Ok Garry, I believe you are perhaps a little bit paranoid about lightning. One thing I have learned is that you don't fly models if you dont want a crash. You don't erect metal in the air if you don't want lightning.

What you can do is to use an optical isolator so the antenna has no electrical connection between the bit in the air and your valuable receiver. When you want to transmit, then plug in the transciever, but under normal circumstances, just leave the opto-isolator in circuit.

I first read about the technique as a solution for preventing RF radiation from vintage regenerative receivers. Just an LED and photo-cell work very well through most of the HF band. The only complicated bit is supplying the LED with a few mA of operating current.

This will not help you if you get a direct strike, but in that event, nothing will.

BR Harry

As a resident of an eastern (therefore colder, and rainier/snowier) suburb
of Vancouver, BC, Canada I can appreciate this. However, see

<http://www.boondocksnet.com/twaintexts/quotes_not_twain.html>

and the article

Kim A. McDonald, "Many of Mark Twain's Famed Humorous Sayings Are Found to
Have Been Misattributed to Him," Chronicle of Higher Education (Sept. 4,
1991), A8.

(Entering "I ever spent" + "Mark Twain" into Google confirmed my suspicions.)

Incidentally, for a good description of why Google works so well see pp.
256-260 of Howard Anton and Robert C. Busby's "Contemporary Linear
Algebra". Some of the bugs in this section of the text were removed by
yours truly -- see p. x of the Preface of the same book.

Different rules here, but they require the same thing (for the same reasons).

Difference is perhaps, that the inspector's here aren't supposed to make up the rules on the fly. To do so would expose the electrician and the testing authority to the risk of manslaughter charges if someone was killed and the coroner found that the breach of wiring rules contributed to the outcome.

Electricians have been convicted of manslaughter in this durisdiction when their shoddy work contributed to a fatality.

Of course if one was not qualified (not licenced) and did such things, it might be more difficult for the prosecutor to make manslaughter charges stick.

I feed my vertical delta loop 1/4 wavelength down from the apex, providing vertical polarization and better take-off angle for DX. And if you feed it with 1/4 wave of 75 ohm coax (as a balun) you will be able to get the SWR down to 1:1.

Mine looks kinda' like this (forgive text-res graphics), seen from the side:

I believe your inspector was wrong. In later versions of the NEC,
there's been several since 1981 and I think 1999 may be the most recent,
there is much to be read about grounding ANY metal interior piping and
ducting. Has little to do with the pipe actually going into the ground,
etc.
Much of the NEC is based on things that COULD become potential hot
spots. Having metal piping inside the house is always an invitation for
some future electrician/installer to make his ground connection there
assuming that it was properly grounded in the first place. I think this
is the scenario the NEC strives to address.

Good point. There has been so much talk about the difficulties of sealing coax that I did not consider simply exposing the shield. How do you make the shield-to-tower connection?

With a half-sloper, the coax shield would be connected to the tower at the feed point (about 40' up in my case) and the base. The shield and the tower would be, in effect, parallel elements. With the small spacing involved (about 2') on 160 - 30 meters, I guess the shield and tower would simply act as a thicker element.

Hi all:

I had a set of them for 40 and 80m up about 20' on the roof. They worked OK

or so I though, until I put up a trapped dipole at 30' for 40 and 80m. The

ham sticks were about 10db down from the dipole on 40m and 15db down on 80m.

You could make contacts on them, but you would not be doing much DX. If I

could have gotten them higher it might worked out better. But with antennas

it a game of compromise. You have do the balance between what you can

afford, how much room you have and how much performance you can stand to

lose.

I use brass shim stock soldered to the braid and then wrapped at least a minimum of 3/4 the way around the tower leg. The joint to braid is carefully sealed with liquid electrical tabe to keep any moisture out of the braid. Then the whole thing is "hose clmamped" to the tower leg.

I believe there is a description as to how they make the commection on the polyphaser page.
I remember coming across a very good page that eve included how to make static balls. Unfortunately I'd have to go search as I no longer have the URL.

I whacked the major portion of the top off my middle knuclke on my left hand working in the shop last night so tis a bit difficult to type.

One of my neighbors where I once lived had a house with metal studs
for the wall construction.
The electrical wires of course all ran through the metal studs. There
are supposed to be plastic
collars where the wire goes through each stud, but are not always
installed by the electricians.
In this particular case the medicine cabinets in one of the bathrooms
would give you a shock
whenever it was touched.
It was presumed that one of the studs cut through one of the wires
making the studs hot. Next
to impossible to find.

That is one reason why it is important to have all metal conductors grounded in a house. You
never know what may come in contact with them.

I'd go out and buy a polyphaser, put it in the line, thouroughly ground it,
and not worry.
Make a grounded bulkhead and ground the end of the coas to that when not in
use. Do the same with the rotor cable connector.

http://www.rogerhalstead.com/tower.htm All leads have poly phasers. The wire
antennas have them up at the remote switch (unused antennas are grounded)
and I have A grounded bulkhead coming in the basement that has polyphasers
for each coax. The system gets hit at least several times per year. I've
lost one polyphaser so far and all the stations were connected.

I did have lightening come in on the phone line to the only equipment no on
one of the warrentied outlets. It took out my ISDN router, Network hub, and
every thing in one computer except the CPU and RAM. Even the power supply
and an external scanner were trashed. Two 40 gig HDs, New CD R/RW
drive...virtually everything. Fortunately nearly everything was backed up
and current

So this summer we completely redid the electrical system and have varistors
on all phone lines as well..

Welll...In the event of a direct strike and a tower the idea is to redirect
the strike into the ground instead of coming in the house. In the case of a
single antenna, the idea is to throw the coax out the window. Just cap it

so it doesn't get water in the coax.

As I said, mine takes about three hits a summer, and there has been very
little damage. Then again the ground system is 21, 8 foot ground rods,
cadwelded to over 400 feet of #2 bare copper in a big network.

He's gonna have to be affuly picky. the metal portion is *only* the meter
and shutoff valve...bout 2 feet long.

Anybody make a good reliable, reputable beam for 40 through 10?

I'd like at least 3 elements on 40. I'd also like most of the WARC bands.
All that metal and still maintain a fair gain. None of these strange
patterns that come off the side that get called a beam like some do.

We'll need to call the NEC people on that one. And I bet the ruling
would indeed be based on how picky the individual answering might be.

Hi Folks,

Can anyone point me to where I can buy K6STI's YO (Yagi Optimizer)
program.

The e-mail address I found on the web has bounced, I can't find any web
site for him with Google and there is no e-mail address on QRZ.com.

Many thanks

Hi Mike -

You didn't say what bands you were after, which might make a
difference.

But I have an 80/40/17 trap dipole mounted as an inverted vee,
about 10' above the roof. I also have a 20/15/10 sloping dipole,
and it's also about 10' above the roof. Both get out very well,
and neither shows any ill effects from being close to the roof.
They do couple strongly into the power wiring and telephone
lines, however.

Good luck, and have fun!

Ed

From: AC6V <ac6v@amsat.org>
Message-ID: <1DbA9.3495$XF5.476923@news2.west.cox.net>
Source record: 131490

For 6M calling and DXing frequencies and where to listen -- see URL:
http://ac6v.com/callfreq.htm

Also get on the DX packet clusters -- either VHF or the web -- See URL:
http://www.cestro.com/pcluster/telnet.html
If there is any 6M activity (skip or sporadic E) it will be posted on the
clusters.

For casual 6M DXing, propagation is much more important than the antenna. I
and another ham here in San Diego used verticals (me cushcraft 1/2 wave
ringo) my buddy with a homebrew vertical dipole. We worked all thru New
England some Carribean, and Alaska and Hawaii on F-skip. On sporadic E we
worked all thru the northwest and some SW from San Diego.

Of course a beam and power will do you better -- but for openers a homebrew
$2 dipole (vertical or horizontal) will do.

Good Luck

Hi Dick,

Currently raining, fairly windy too. There's no point in saying when this report is made, aside from the timestamp that comes of posting this, as it has been true for at least the past three days. As has Roy, I will offer my own school's link:
http://www.atmos.washington.edu/images/vis1km/200211121730.gif
a wider view offers a glimpse of why we call some storms the "pineapple express":
http://www.atmos.washington.edu/images/vis4km/200211121700.gif
The arc of clouds is something that also visually demonstrates how some weather allows us to work Hawaii with VHF tropospheric ducting.

And yes, it is a dry autumn so far (winter will get here soon enough as it is). However, dry as a description is relative. Less than 50 miles from here the annual average rainfall is in excess of 200 inches. Seattle sees only 40 of them. This 40 inch average is fairly similar to New York City, except we get it spread over 10-12 months instead of the majority of it over 2-4 months of a wet season. By the

way, within this same 50 miles is a region called the "Blue Hole"
where the rainfall is less than 20 inches a year.

It's like one of the guys said: it isn't the greatest thing around, but it
will work. You might not be
able to put a BIG signal on the air, but when faced with constraints such as
finance, CC&Rs, space, and reluctant spouses, ya does whatcha can. Best
thing to do is to try it, fiddle with it,
and see what happens.

Paul,

I have the 269, and find that on the lowest frequency range I measure within about 1 ohm of the DC resistance value. (A 47 ohm 1/2W resistor, which is actually 49 ohms). The resistance drops with frequency. I think I was reading 43 ohms at 2 meters. Do not use a dummy load, they (at least mine) have spurious resonances outside of the ham bands. How far off is your 259? Suggest you write or email MFJ at www.mfjenterprises.com

The "cheap" cat-5 isn't rated for burial or exposure to the
elements. Also, it is only 24ga. Might have some voltage drop
problems if your remote switch draws much currrent.

Hmmm. It's been 20 years since I was on EME but I do have WAC on 2
meters, so I think I can speak to that. And most of my professional
career involved making r-f/microwave measurements, including some time
on both a open field antenna range and an indoor anechoic compact
range so I have a feel for that too.

I can tell you that I *never* knew what the impedance was of the Yagis
that made up my modest EME array. I knew to a fair degree of accuracy
what the SWR was but not the impedance. I sure as hell didn't have
the ability at home to measure gain or pattern with any type of
accuracy.

Furthermore, I knew with little uncertainty what the noise figure was
on an HP8970 Noise Figure Meter, since I had the ability to reduce the
uncertainty by making vector impedance measurements on both the source
and the preamp. However, I didn't know what the NF was when actually
connected to the antenna.

But I did hear echos, made a lot of EME and tropo contacts and was one
of fewer hams world-wide to make a two-way with Owen, W5LFL, in the
first ham operation from the space shuttle. My report: "N7WS, you're

the loudest signal we've heard in the spacecraft." I think that means 5x9 but on FM I'm not sure. (Four long-boom Yagis and 1500W beats a five-watt handitalkie every time)

So I reiterate my support of Roy's earlier statement. "It's fortunate that we can so often get by without really knowing what the impedance, gain, or pattern of our antennas really are."

We really can. Honest.

Chip,

I didn't consider PVC because of UV break down but CPVC solves that it looks real good in most places unless the high strength is required. For a great many things it is ideal.

Thanks

Fiberglass is great material but very annoying to machine. Wear full
berating protections and run a vacuum with the canister out doors picking up
the dust at the dust. It is not good stuff to breathe.

|He's gonna have to be affuly picky. the metal portion is *only* the meter
|and shutoff valve...bout 2 feet long.

Then that is the portion that should be bonded to the service entrance
ground.

The last I checked, ionized water is conductive and I'm pretty sure
the faucets in your house are metallic. So dispite the plastic
piping, your faucets are connected to the whole water system.

I found coastal WA to be rather remarkable. What you have there is a rain forest. Not a tropical rain forest, of course, but a rain forest nevertheless, quite lush with the foliage of one. Then when the Coast Starlight crosses the mountains to the east side, suddenly you're in a desert.

The director end will be the end with longest spacing to the driven element, and the reflector end will be the end with shortest spacing to the DE. True for any 'standard' three element yagi.

Pete,
A 'Hamstick' is a helically wound 1/4 wave fibreglass
antenna with an adjustable 'stinger'. Since it's a mobile
antenna it doesn't need radials unless you're mounting it
on a non-metalic object, just like any other 1/4 wave
vertical antenna.

Since a couple of us locals have acquired Stealths, every single "screwdriver" (including HS) user who has seen them has said that will be his/her next antenna. Without exception, we've also been told our signals have never been this good before. BTW, Charlie builds --as far as I know-- the ONLY screwdriver-type antenna with a four-inch diameter coil.

Screwdriver antennas take a beating, apparently related to the mechanical aspects of get shorter and longer as they tune. Apparently, maintenance is required on a continuing basis. Stealth coils are unique in that the length doesn't change. All tuning is internal and the coil is sealed from dust, dirt, rain, etc. Stealth users don't do maintenance... they just talk. Is the Stealth worth the price? Depends on how serious you are about mobile ops and whether you hang out on 80/40 meters or above. The real value of a big-coil, high "Q" antenna will be primarily on 80 and 40 meters.

2386. Anybody tried this 160m antenna ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-13 13:49:56 UTC
From: Andy M <andrew.markham@virgin.net>
Message-ID: <_JsA9.825$CT5.107495@newsfep1-win.server.ntli.net>
Source record: 131425

Hi All

Anybody tried this antenna. I found it on the following web site
http://www.g3ycc.karoo.net/ant1.htm.

Seems ideal if you have a small garden (like me) to get on 160 meters, if it
works ?.

''It consists of 140 feet of insulated wire, the first half of which (70
feet) is
space wound on an insulated tube. I used glass fibre tubing which was to
hand,
but PVC may be used also. Tube is 1 1/2 inches in diameter and about 5 feet
6
inches long. The turns are about 0.5 inches apart. Mount tube at top of
mast. The other 70 feet of wire
acts as a loading wire and slope down from the top of the coil to near
ground
level. The system is coax fed to the base of the coil, with the shield or
braiding going to earth.''

The only suspect point I can see about this antenna is, if the tube is
mounted at the top of a mast, it means your going to have a very long earth
run from the coax feed point to ground.

Andy

2387. Re: High Serria 1800DX

Source record: 131426

I don't agree. Unlike Lonnie, I have owned both. The High Sierra is better
quality than the Stealth. I bought the Stealth first. I had to send it back three times because the coil kept jamming. Here's what happens, the supposed high quality coil is made from a platic disk. When you run the coil all the way up or down, IT JAMS! Then, you must send it back to the factory..Charlie's garage, for repair. I also had some of the fingerstock break off.

My HS1500MKII has never jammed. It doesn't use fingerstock. It has never been a problem. It is a beautiful antenna. It is really made in a shop with employees who do care; not someone's garage. I have recommended the High Sierra antennas to mind friends and they are happy too. Buy the High Sierra.

By the way, when I tried to get my money back from Charlie, he refused. As he says in the poorly written instruction book, when you buy it, it's yours! No refunds.

73, Fred

2388. Re: Pattern of *Tri-Di-Pole*+++

Another couple of antenna misnomers.

Rule 1: Then how do explain the THOUSANDS of feet of grounding wire used in broadcasting set-ups? Or how do you account for the many hundreds of feet of "artificial" grounding radials when operating an elevated ground plane antenna for 40 meters? (i.e. approx. 33 feet times 4 radials coming down at a 45 degree angle.)

Rule 2: When working DX on 6,10,15,20...the higher the better is NOT the best "rule of thumb". Antenna height equal to wavelength offers the best angle of DX.

73, Mike

Please, no jokes about the Web-TV. My 'puter is all tied up with ham stuff.

See URL:
http://www.hamstick.com/

They can be used in several configurations

The verticals will require radials or a ground plane such as a car body for mobile use.

Two end to end can be used as vertical or horizontal dipole.

They are generally two-piece MONOBAND ANTENNAS (shortened design with accompaning reduced band width and efficiency as in all shortened antennas)

2390. 2M antenna for marine band?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-13 16:03:07 UTC
From: cprstn54zz@att.net
Message-ID: <3dd270de.272959406@news-server.optonline.net>
Source record: 131429

I need some help interpreting these results. The purpose is to see what I lose if I use a 2M ham antenna for marine VHF. What I gain is domestic tranquility by not having a second antenna in a visible place.

I used a VX-150 ham handheld and an HX-460S marine handheld. My measurements were with an MFJ-924 VHF meter/tuner. The feedline is RG-8X 20 ft long.

Each radio had a fully charged battery and was also powered by the wall wart. Each showed 6 watts and SWR=1 when connected to two different antennas respectively resonant for each band.

When I tried the marine handheld with the ham antenna (a homebrew J-Pole), indicated power dropped to 4 watts and SWR was 1.25.

Does this necessarily mean I am losing roughly 33% of my signal by using the nonresonant ham antenna for the marine radio?

Hi Guys,

I am looking for an article in Ham Radio Magazine, March 1968.
The article is "Modifing the Yaesu FT-310 for 30 Meters"
I would be interested in the issue or a copy of the article.

Thank you very much,

WA4MNT

Pete,

I was just thinking the same thing. Many hams (including myself)
often get licensed and then run into difficult situations (lack of
money, lack of a location) for putting up a station. It is possible
that the original post came from a guy who hasn't used hamsticks
before, despite how long he has been licensed.

I was licensed as a Tech Plus in 1994, and I had never heard of a
hamstick until I got my General class ticket about a month ago.

I guess I'm a LID.

It's guys like this that keep people from asking questions and

Hi,
I have a Gap Challenger, but the manual which I was
able to download from the net has very poor graphics
which are basically unreadable.

There are only four graphics in the manual. If someone
could scan them and e-mail them to me I would be
eternally gratefull>

I am trying to beat the snow -- we've already had four
inches, but it is melting and I may yet get a window of
opportunity to put the GAP up, but first I need to know
how to properly assemble it.

Thanks in advance for any assistance...

Thank you, Scott, for your note.

Mr. Bessler has me pegged, I suppose, as a LID. I must confess that when I got my Advanced ticket I studied very hard (I even got my code speed up above 20 wpm for the Extra test) and got the highest level license I could. But then, I settled into enjoying ragchewing on the CW bands and have since forgetten much of the theory I learned.

I do my best to put out a clean signal and clear, solid copy code that I feel I can be proud of. I am civil on the air to everyone I meet and, therefore, I hope, a credit to our hobby. But, it's true that I haven't devoted myself to the technical side of radio as much as I should since my life has other endeavors which consume me.

If that makes me a LID, well so be it. But before the Besslers of the world try to drum me out of the hobby they might consider that after they have thinned the ranks, commercial equipment would disappear for lack of a market and amateur radio would become a political orphan. So, I'll muddle on.

Pete

Virtually every question on this newsgroup could be answered by independent study and research, John. I thought, though, that the point of the group was to provide a forum for some friendly chat and exchange of ideas.

You and Bessler add nothing to the hobby, serve only to diminish yourselves, and if standing eye to eye with me, would likely wet your pants before managing to be so rude. Unfortunately, this format sometimes brings out the worst in people.

There's no earthly reason why any ham should be an expert on any
particular commercial antenna. On some level, all antennas are
difficult to understand, and if someone asks a question that might lead
another to have a better understanding of the fundamental
operation of even simple antennas it's a good thing. The surest way
to betray your own ignorance is to make fun of someone else's.

Tom Donaly, KA6RUH, a fellow LID.

2405. Vertical Yagi Simulation in EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-14 00:03:45 UTC
From: Mike <"scifiguy at starband dot net">
Message-ID: <i9n5tu8vfqa67f413po54bfnjelkufq3ma@4ax.com>
Source record: 131444

I downloaded EZNEC Demo, and started playing with a vertical antenna design for 11 meters. I wanted to optimize for low angle gain, and a moderate amount of directivity, while keeping the construction simple. After varying the lengths of both elements, and the position of the director, I came up with the following (please refer to the EZNEC output below).

Since I'm very new to this kind of thing, I don't suppose for a moment that I've come up with a new design, so can someone tell me what this would be called? It's sort of a lop-sided Yagi, but none of the lengths come out right for a standard Yagi, according to the antenna references I've got. Unless I missed something, it also has better gain and lower angle than a textbook two element Yagi that has been tipped vertical.

My second question is: Since the elements are kind of long, could I use some linear loaded mobile monopoles, cut to the appropriate lengths (like a Firestik 5/8 wave for the driven element, and a trimmed down Firestik 5/8 wave for the director)? Come to think of it, is the driven element actually a 5/8 wave that just ended up physically shorter due to end effect? It seems like it is a little too short to be 5/8 wave, but I don't know for sure.

If I could match the impedance, and use something like a couple Firestik KW6's, it might make a neat little package (and a fun project).

--Mike

Thanks to Pete Norloff KG4OJT I now have the graphics. I should point out to anyone else in my predicament that the graphics Pete provided differ somewhat from those in the PDF manual available on the Gap antenna sight, and the PDF manual from Gap differs from the one that Pete has. In any event, I have enough now to begin setting things up -- as soon as the snow clears! If anyone else needs the info, I will gladly pass it on. Thanks again to Pete! Love that spirit of Ham Radio!!!

If I remember from the olden days ... that problem was 'solved' [almost]
by the Heisenberg Uncertainty Principle. You can know ALMOST where it is
and Almost what it's momentum is BUT not both at the same time.

So, it can be measured with a defined amount of uncertainty!!

Basically YES!

I doubt the VSWR reading. It should be higher!

The radio is shutting down the power level to minimize heat [damage] in
the output transistors.

Good Day Ken.
I'm afraid you are right about the power loss
with a 146 MHz Jpole antenna.
The marine band is around 156 MHz so the antenna is about 10% too low in
frequency.
In fact I'm surprised that your SWR was only 1.25/1. I've found that the
Jpole is a useful omnidirectional antenna but its bandwidth is limited
like any other antenna.
Since the Jpole is a pretty unobtrusive antenna anyway wouldn't it be
possible to disguise it as something else? I've even seen them built
inside a fibreglass mast or flagpole and give good results. After all the
marine antenna is going to be about 10% shorter than the ham one.
I've just refurbished my 2 metre Jpole and I'm afraid I wouldn't like to
drive an expensive handheld into an RF load which might cause damage to
the TX.
Hope this helps 73 Cliff Wright ZL1BDA ex G3NIA.

> element.

I'd think so, too, Bill. Unless there is some way to differentially excite them, they should just carry in-phase currents (distinct from the transmission line currents inside the coax). The closer you can keep the coax to the tower, the better. At the base of the tower, what happens to the coax? Is there some place it can "give up" its antenna current to the ground? That is, is the coax then burried, going to the shack?

If you want to keep antenna current off the coax, you can put ferrites around it. If you do that where it's running parallel to the tower, I suppose the tower will just couple to the line. But it might be worth doing at the bottom, to encourage the current to stay on the tower. That has the effect of exciting the line composed of the outer conductor of the coax and the tower, but I think just in a way to get the current off the coax at the bottom.

So...what is the problem you're trying to solve? I'd question whether you'll notice any significant difference in signals whether you tie the coax outer to the tower at the bottom or not. If you don't, is there some other need to do it? Could that need be addressed some other way? (Why do it if you don't need to?)

Cheers,
Tom

I've seen much higher swr just by a whip being cut for the wrong part of the 2 meter band -- you're 10 mhz off, so expect to lose some power.

And easy fix would be to shorten the 2 meter antenna to make it resonant on the marine band, then alligator-clip a pigtail to it to make it resonant on 2 meters. Actually, a small alligaor clip, by itself, might be all that's needed to add to the tip of the antenna.

> I have to maintain 50 ohms to avoid massive reflection?

You can, but as Gerry suggests, a directional coupler is probably a
better solution...or even just part of a directional coupler. If you
put a 500 ohm resistor from your line to the counter input, and the
line to the antenna is about 50 ohms, you'll waste about 1/12 of your
power in the 500 ohms, and get about 1/11th the voltage across the
counter's input. But if you used a transformer, either a current or a
voltage transformer, you can get the same voltage to the counter while
wasting only about 1/11^2 or 1/120 of your power. It's perhaps a bit
harder to construct, but maybe worth it if you want to conserve all
the power you can. (1/10 of your power is only about .5dB...generally
not enough to get upset about...but of course antennas that can claim
0.5dB more gain try to make a big issue of it in some markets.) For
higher power from the transmitter, it can keep you from having to use
big resistors to handle the power dissipation of the attenuator. You
can make a coupler with discrete toroid transformers, or with
something as simple as a piece of insulated wire slipped under the
coax braid for a couple inches (where it will "see" a lot more field
than you find outside the braid).

Is 500 ohms enough? Is your transmitter only 1/2 watt?

Cheers,
Tom

Well, Gus, I won't argue the relative merits of the two with you since I have no personal experience with the HS and obviously you do. However, I will say that you are the first person I have heard from who claims to have had any problem with the Stealth. Well, make that "second guy." I did hear about one, in Europe, whose coil developed "sweat" inside. Charlie sent him a new coil along with a specialized tool required to install it... no charge.

I have run my coil up against both stops several times with no problems, and held them there for 1/4-minute or more. If Stealth coils ever did jam or break, it must have been fixed a year or more ago. My previous coil didn't jam or break either. Charlie now furnishes two tiny thermal circuit breakers, to go in the control lines, which temporarily cut the power when this happens.

Refund? Never knew anyone who asked him for one. I do know he will give you a decent trade-in on your old Stealth antenna if you're upgrading to something newer and better. Virtually unheard of with antennas. I have been most impressed by his customer service... reminds me of TenTec's legendary support.

Glad you're happy with your HS.

Hello Everyone

Having read all the posts in this thread, I can find nothing really wrong
with KG0WX and his
reply to your Orig Post Actually it was kind of like somebody who grew up In
the U.S
while never having heard of McDonalds.

A Hamstick is pretty much like the McDonalds's of the mobile HF antenna
world.(Cheap and made in Mass Quanitys)
not everyone has used or owned one but every Amatuer radio Op i know of (
All classes) know of the hamstick
heck, i even heard of hamsticks and I wasn't active on HF until about 1-1/2
Years ago when ken (KG0WX)
encouraged me to upgrade to general class

>But before the Besslers of the world try to drum me out of the hobby

F.Y.I : as a matter of fact, If it wasn't for Ken i would have never been
able to reassemble my shack
due to a low cash flow
Actually he had gone out of his way to buy gear for me with no more than
a " pay me what you can when you can " from him....Now thats a Elmer.

I serioulsy don't think ken really ment anything bad about the comment...so
settle down, take a
deep breath and relax. Amatuer radio is a public service/Hobby not a religon

just my 1/50 of a $

Mike, N0JVT

If we must fight about somthing how about the Ham Vs. CB'rs..... it 's much
more interesting :-)

The J-Pole is a temporary, unobtrusive antenna attached to a nearby
dormer about 12 ft up. It is blocked for approximately 170 degrees by
the rest of the house. I used it for the test.

The permanent antenna is an 8 ft long tri-bander that is going 28 ft
up on the gable end of the house. I didn't test it yest, but will
now.

Everyone seems to think that the SWR should be higher. Is there a
simple test to see if the meter is working? Like switching the leads?
Then I should be reading reflected power (which should show very low)
and SWR should be very high.

If the band is open, you do not need much of an antenna system or high power at all. If the band is closed, all of the antenna and power in the world won't make much difference when working DX.

The fancy antennas come in handy by giving the operator the ability to quell the voices of other hams when dealing with a weak signal.

I agree with AC6V in that a Cushcraft AR-6 is just fine for the casual operator. An MFJ six meter tuner can stretch the antenna's ability to work all over the six meter band.

Hi There,

I wonder if anyone can help?

I'm trying to think of ways to improve on my 40m half wave dipole and have a couple of ideas.

One idea is to put 2 40m half wave's together on the same balun so they fire at the same time, but one dipole would go East to West and the other would go North to South.

I wonder if anyone has ever tried this, if so how good is it?

So if anyone else has any more idea's for a 40m antenna let me know I would be interested.

Oh by the way my garden is 100feet long by around 22.5feet wide, and I also have permission to use the bottom 30feet of the nextdoor neighbours garden!!

Cheers.....

M0DCM Dave

Source record: 131460

Your idea will give you a dipole-like pattern (but filled in a little), with maxima to the NE-SW or NW-SE depending on the relative phasing between the dipoles. I also don't see how you'll fit these on your lot. Here are a few suggestions:

1. Put two dipoles at right angles like you suggest, but feed one directly, and the other through a quarter electrical wavelength (23'2" at 7.0 MHz for solid dielectric coax) 50 or 75 ohm coaxial cable. This will provide roughly a 90 degree phase shift between the dipoles and result in a more nearly circular pattern. You could also run a separate feedline from each to your shack and switch between them. But again, I don't see how this will fit.

2. Put up an inverted vee. This will give you improved performance off the ends, compared to a dipole. But you'll have to get it higher than a dipole to get comparable low angle radiation.

3. Use a vertical, with at least 6 - 8 ground radials. My experience is that this is pretty comparable to a dipole at 40 or so feet on 40 meters, but it depends heavily on the quality of the nearby ground.

4. Put up two verticals spaced a quarter wavelength apart, each with half a dozen or so ground radials. If you feed them with equal currents and 90 degree phasing(*), you'll get a good front/back ratio, which will help you reduce interference. You can switch them in either of two directions with this pattern. You can also feed them in phase to get an approximately omnidirectional pattern with better efficiency than you'd get with one. Feeding them out of phase will give you good nulls off the side, but the efficiency is likely to be low, so you might want to restrict this phasing to listening only.

5. Put up two verticals spaced a half wavelength apart, and feed them either in phase for a broadside pattern or out of phase for an end fire pattern. With two elements, these phasings are easy to achieve. For the in-phase pattern, just feed both with equal lengths of cable. To change to the out-of-phase pattern, just switch a half electrical wavelength of cable in series with one of the lines. Both patterns have good nulls at right angles, which can help you with interference.

Roy Lewallen, W7EL

(*) Unfortunately, getting this current ratio is more difficult with parallel verticals than with the crossed dipoles. To learn how to do it, see Chapter 8 of the _ARRL Antenna Book_ and/or "The Simplest Phased Array Feed System -- That Works" in the _ARRL Antenna Compendium_, Vol. 2.

Canyon,
I have the complete set of Ham Radio on CDs and do not see an
article with this title in any issue. Also, I don't think we had 30
meters back in 1968. Did you mean QST or perhaps 73 and a different
year?

May I suggest one of the six meter antennas from KMA Antennas? Both will cover the whole band with swr under 1.5 and have gain equal to similar sized yagis. The website is www.kmaantennas.com.

Ooops. Failed to recalibrate the meter for this rig. When done
properly, SWR is 2.5 -- not 1.25.

Well Pete:

I would have told you the same to your face, then the I would have answered your question. You may notice I work for a university. One of the main points of higher education is to show you how to do your own research. If you had done some research, you would then be able to ask a question that has some usefulness. As, does it work as they claim, is there anyway to make it work better, or will it do what I want it to do. Above all you would have had the pleasure of discovering something for your self. The things that a person remembers best are those they worked for on their own. If you do it often enough you too can be a "know it all" like I am.

There's a little book put out by Champion Radio Products that compares hf verticals. See their web site.

You can go to the ARRL site, the members only section (you have to subscribe to QST), and look at their product reviews.

You can go to eHam.net, and look at the product reviews of antennas, there.

There are also some pretty good technical papers on vertical antennas at the Bencher/Butternut web site.

Source record: 131324

Hello.. I've got a question maybe some more knowledgeable hams can answer..

I've got an IC-746Pro connected to a Superantenna MP-1 that I just put up.. (I just had to move into an apartment, so unfortunately, that's my only solution at the moment..)

Tuning it to the best SWR is not a problem; between the sliding loading coil on the MP-1 and the built-in tuner on the IC-746, I'm able to get an SWR of < 1.5:1..

The problem, however, seems to be recieving.. My S-meter is always at 50%, and there's just noise all over the band, on every band.. Nothing but the absolute strongest signals make it through, and it's very noisy when they do.. I'm thinking maybe this is a grounding issue, perhaps??? Kinda a tough thing to remedy in an apartment if so.. Also, I have huge AC units on either side of my patio - so I'm sure that's not helping.. Is there anything I could do?

Also - a question on the counterpoises.. How exactly are those things to be laid out?? The instructions were very minimal.. I imagined they should be at 90 degrees from each other, perpendicular (there are 4 of them..) However I'm guessing if my SWR is under 1.5 i've got that laid out right and it's tuned right.. so that's what leaves me with the grounding issue on the noise..

Thanks in advance for any suggestions..

73's.. KC2DZE

Vertical antennas were discussed in the last few weeks on uk.r.a - so
I suggest a Google Advanced Search should turn up the thread(s), and
it will save contributors to those thread(s) having to type it all out
again.

2443. Improving Cell Phone Reception

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-14 19:04:59 UTC
From: bananaman165@hotmail.com
Message-ID: <89761e12.0211141104.31c7314f@posting.google.com>
Source record: 131332

I was reading the archives here about cell phone antenna boosters and other such mysteries. Well, I can't comment on the devices sold to the world for somewhere between $0.50 to $29.95 depending on how rich you look to be...

But I CAN comment on an experiment that I just tried. I have a Motorola V60g 1900MHZ GSM cell phone. In my office at work, I either have "NO SERVICE" displayed, or at most 1 bar of signal on the digital meter (I realize this means very little, but bear with me a bit...)

I opened up the battery compartment, took out the battery, and inserted a paperclip, cut to about 2.5" so it would fit the compartment. I aligned the clip with the antenna stub. No actual connection was made to anything; I just dropped the clip into the battery compartment. I replaced the battery, closed the phone, and wooooooaaaaahhh: I have 2 bars of signal where I had "NO SERVICE" before, and 3 bars where there used to be 1.

I even made a phone call to a friend who said "you are breaking up a bit", but when I moved to the 3 bar area they said "oh, now you sound fine".

Sooooo.... Rather than spend even $0.50 (or the unconscionable $29.95!), try a paper clip first!

Regards,
Dave

PS: If you are unable to find paperclips in your area, email me off-group with your credit card number and I will ship you one for $29.95 plus $5.95 shipping and handling. If you act now, I'll throw in a second paper clip for free!

Good question, Wes! Maybe the 5W QRP rig has no such readout (and the
trial with the other radio is just a test to see if it works
properly)?

Cheers,
Tom

Well, let's see. A meter is a little over 3 feet, right?

Then 40 meters is more than 40 * 3 = 120 feet.

I'll leave it to you to divide this by four to find a quarter wavelength.

2447. Broarder bandwidth

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-14 19:18:34 UTC
From: aunwin@insightbb.com
Message-ID: <85ed38d.0211141118.72fca4d7@posting.google.com>
Source record: 131334

Looking at some older notes of mine I ran across
what I consider to be a better feeding mechanism
for antennas.It never gained interest even tho
nowadays modeling is widespread. Can anybody
point out why it is not in general use for technical reasons.
Looking to broaden the bandwidth of antennas I fed a unsevered
dipole (I like strong centers of antennas) with a small SEVERED
dipole which had a 2 inch gap at the center and some distance
beyond the original dipole point of feed if a delta feed was
used direct to the original dipole.
Feeding just the short 'severed' dipole without it being near
another radiator would have been a disaster. But when coupled
closely to another radiator the bandwidth of the larger dipole
broadened considerably. Apparently the current flow into the
capacitive coupled feeder dipole chose its own point of flow to the
main dipole for minimum resistance, somewhat similar to what
one would obtain by adjusting the feed point of a directly
fed antenna. This method of feed does not give the same frequency
flexability obtained by varying lumped constants, but for those
with monobanders it resolves the need for special 'cutting'
arrangements for DX band portions. I called this 'Capacitive Coupling'
which may be a misnomer that frightened people away from this concept.
I would apreciate any technical comments. No, I have not mentioned
'gain' and yes, I did write it up in a patent many years ago but it
never gained professional review or a write up in a book.
I would prefer no spamming this time around if possible against
introducing a new idea.

Isnt this what Mosley did on their Classic TA-33 and TA-36 design of years ago? A wire was inside the driven element of the Triband element and that is where the coax was hooked in the center of same. Its been a while but sounds about the same to me.

Chuck,

I used a TR22 with a "Junior" tribander for several years. A very strong wind might turn it slightly. Just be sure that the antenna is resting right on the top of the rotor. It won't take any bending moments from a mast of any length. Even raising the antenna 6 - 8 inces will double the load on the bearings. I did have a small VHF beam a couple of feet above the tribander.

|Good question, Wes! Maybe the 5W QRP rig has no such readout (and the
|trial with the other radio is just a test to see if it works
|properly)?

I dunno... he said somewhere along the line, "I had hoped that its
antenna would pick up stray radiation when I TX from my FT990."

I haven't really followed the thread so I don't recall anything about
a QRP rig.

James

without wishing to sound negative - do you really want to shell out hundreds of quid for a multiband vertical?

I have a Cushcraft R7 - super antenna, well constructed, not too unsightly and works well on all bands 40-10m. Cost about 350 quid if I'd have bought it new. I have a 102' doublet that consistently gives +2 S-points better on all bands (except 17Mhz) for almost all contacts. Cost about 20 quid if I'd have bought the wire new.

If you have the space for a vertical plus radials you can get a 44' doublet in and outperform the vertical in most directions on 40-10m at no cost. A 10m fishing pole and some ingenious wire work will give you great performance for well under 100 quid.

I'd recommend a visit to L B Cebik's site (www.cebik.com) and a purchase of John Heys Wire Antennas book book before splashing out.

2467. electrostatically shielded antenna NEC model?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 00:13:17 UTC
From: "David A. Howard" <dahoward@pacbell.net>
Message-ID: <x_WA9.519$ql2.72908113@newssvr21.news.prodigy.com>
Source record: 131356

While I've been quite successful in the actual construction of 1-wavelength shielded loops, I've discovered I'm clueless as to how to model them using EZNEC/4...

I've made them out of RG-405 rigid coax, and printed micro-stripline vesions on FR4, and 3-mil polyimide, and polyester flexible laminates... I'd like to try the same technique or possibly stripline on/in high dielectric ceramic materials (dK >20 <100). I've already tried a physically scaled down microstrip version on Arlon 1000 (dK10), but the results weren't what I expected. Before I fork over the cost of printing on multilayer LTC Ceramics, I thought it might be a good idea to model the beast to get a better understanding of what is going on...

Unfortunately, I haven't been able to construct a model in NEC that is close to rigid coax, or low dK microstrip antennas I've already built/tested (physical size, gain, impedance, etc...). I realize their are dielectric effects that I wouldn't be able to model in NEC, but at this point I would be very happy to just get an air dielectric equivalent shielded loop in NEC.

Any ideas/examples out there?

>
> Ken KC2JDY

No! The VSWR you are reading is probably correct IF [I say again IF] line losses are ignored. The VSWR at the antenna should be much higher BUT line losses 'fake your meter out'. The coax losses are [may be] attenuating the reflected portion of the signal.

A simple example makes the point of losses in coax: Assume 6 dB of line loss and 10 watts output. Then 2.5 watts gets to the antenna. Assume a total mismatch at the antenna so that all the power gets reflected. Then, only 0.625 watts gets back to the VSWR Meter. VSWR would read about 1.4 to 1 where it is actuality infinity to 1 at the load!

If you have a dummy load that is reasonable at 150 MHz then a simple test can be run to check coax losses. Connect the far end of the coax to the dummy load and measure the power into the coax [with your VSWR meter]. Do not change VSWR meter sensitivity settings. Now move the VSWR meter to just before the dummy load and measure how much power is getting there. Your line loss is calculated by:

Loss = 10 * Log (power at load/power into line) in dB.

I have both. The Autek has been a disappointment since
day one. I love the 259B! Please don't ask for
explanations -- too complex and too much to explain.

I don't want to drift too far OT for this group, but what you suggest isn't necessarily so. In these days of continuing espionage, number groups via SW have proven to be one of the more secure methods of encryption. There have been two incidents in recent years involving Cuban agents that reportedly used this same system coupled with transcription keys called into them via a pay phone. In both cases the mix apparently went into a computer for actual decoding.
One of the benefits of using numbers for encoding is to minimize the possibility of errors, simply because there's only 10 digits as opposed to 26. One single error may hopelessly garble the entire transmission.
Anyway, a good read on this whole bizness is "Between Silk and Cyanide" written by Leo Marks. Its a lively tongue-in-cheek read by the gentleman who, in his early 20s, revolutionized and perfected this type of coding for the Brits at Bletchly Park during World War II.

Hi,
I like to know how will be the electric field distribution for a quarter wave patch(shorted at one end) for the dominant mode, first higher order mode and next higher order mode. Kindly help. I would really appreciate if i am given some links or papers where i can look for it.

Thanks in advance.

I won't dispute that the numeric codes aren't used, and for
the
reason you specified. The 5 number groups for weather have
been
used internationally for years, and I would suspect that a
continuing
broadcast would not likely be clandestine. Also, this
transmission
was in the middle of an international band (although
clandestine
radios can operate anywhere), and lengthy. It puzzles me
that there was

an indication that the station was Spanish -- more
information
might be needed to make a better guess. The Engigma and our
later
counterparts used the five letter groups. I would suspect
that today, with
the advent of computers and satellites there are much better
means
of communications between controllers and agents -- high
speed
data and burst transmissions. I spent many years as a naval
radio
operator, and a number of years as a naval officer
conducting elint
and comint operations -- my offering with regard to nospams
query was
just a 'hunch'. Its really anyone's guess. The

Just to make sure it's not the current antenna that's screwing things up, you might connect an odd length of wire to the center connector of your your rig's coax plug (for receiving only), and move the setup around the apartment, to see if that changes your noise problem. Try the rig on different AC plugs. You should be receiving something, other than the loudest signals -- unless you have a really serious noise problem.

(You might also make sure your RF gain isn't turned down too low; that could give you a lot of hiss, with only the loudest signals getting through.)

Source record: 131364

Henry,
The biggest difference between the two is how information
is presented to you. The MFJ is more specific in that it gives
you definit 'numbers'. The Autek gives a more generalized
presentation (a response curve) and you have to interpolate
from that. So it really just depends on how you want to be
given the data. Both work equally well.
'Doc

My single story home is on a lot 120' x 60'. I live on the east coast
and would like to work at least the states and some DX.
What would be the best design antenna to use on 160m
with my property laid out as shown below. Any ideas or a link to a webpage
with drawings or design would be appreciated. No unsightly
antennas can be in the front yard...only a wire maybe to the light pole.
I also prefer not to use a tuner except to expand my bandwith.
Any help would be greatly appreciated.

73,
Andy WD4FY

The "coupler box" is called a bias-T. It has three ports:

The D.C. bias port. This is the connection to the power supply.
Inside the coupler box there is an appropriate sized inductor to the
other two RF ports. RF port #1. This is the input port. The inductor
makes the connection from the D.C. port to this port. RF port #2. This
is the output port. A capacitor of appropriate size connects it to RF
port #1.

The inductor stops the RF from going to the power supply but allows the
D.C. to reach the input port and on to the amplifier to power it. The
capacitor stops the D.C. from reaching the radio.

The size of the capacitor and inductor are calculated at the lowest
frequency of operation. You want the reactance of the coil to be > 10
time the impedance of the line it is inserted in and the capacitor to be
a small fraction of the same. The coil needs to carry the current
necessary to power the amplifier without saturating.

The same capacitor and coil will be used in the amplifier in the same
way for the same reasons.

5 letter groups were widely used by Soviet block clandestine communications. To decode you needed to have the same book as the encoder, number gave reference to page, line and word in the book. They used target language for particular country (like Cuba in Spanish).

For moron spies they used phone, for advanced CW :-)

How about a horizontal dipole? :-) At my QTH, vertical noise is 2 S-units
higher than horizontal noise rendering a vertical virtually useless for me.

Henry,

The MFJ can not tell the difference between capacitive and inductive reactance; BUT it has a lot wider frequency range. I went with the MFJ 269, which also covers 430-450 MHz. If I was strictly HF, I probably would have gotten the Autek. Found I can not use the MFJ on 75 meters when the band is open, too many strong signals give me garbage readings. OK during the day.

Why don't you download both owner's manuals. They are online.

Rob,
Probably because the ARRL has three 'sets' of antenna
projects/designs. They switch them about every 6-7 years.
Check back in 2008, or maybe 2012 edition of the Handbook,
it'll probably be back in there by then...

The trick to increasing the bandwidth (other than introducing loss) is to devise a network or feed system geometry that generates a reactance that changes with frequency at about the same rate as the antenna does, but in the opposite direction. It sounds like you've done this. A doubled bandwidth would certainly be of interest to 75/80 operators at least, so I imagine it's not in general use either because it's too much of a mechanical nuisance, or nobody has heard of it. Have you published it somewhere? Do you have any measurements showing the bandwidth improvement?

Probably an Inv L , or maybe shunt feed your tower and use top loading
wires. Seems to me the inv L would be easiest. You could run a wire up
"tall tree" as high as you can get it, and then just run the rest of
the wire off horizontal any way you can squeeze it in. The top wire
can make an L looking from overhead, and it's not going to hurt it. If
you could plant a few ground radials, the antenna would be fairly
efficient. The shorter the vertical , the more critical the ground
system. I always prefer a full size wire if at all possible. Thats why
I would probably prefer the full length inv L over a top loaded 40 ft
tower for general use. The tower would be good though if it had a lot
of radials under it. MK

2496. Re: Autek or MFJ ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 12:15:05 UTC
From: G&R <"stop the spam"@limbo.hell>
Message-ID: <gv5B9.14641$QD6.1467735@news20.bellglobal.com>
Source record: 131385

I have both the Autek RF 1 and the MFJ 269 (Got the MFJ to do 440mHz). The biggest difference between the two besides that are:

1. The SWR Readings are slightly different (Autek give slightly higher readings) There are a couple of articles about this in a back issue of QST if I remember correctly)
2. Autek gives a Z value directly.
3. Size. Autek is small fits in your pocket and is easy to handle on the tower.
4. Batteries. The MFJ eats them (10 AA at a time), the Autek one 9V cell slowly.
5. The MFJ 269 can take specific readings directly without doing math. Select it and Read it.

Having experienced both and having the option to use both I would be hard pressed to choose one as each has very good characteristics. You must decide which application you will use most and then decide. (Or if you have deep pockets, get both Hi, Hi).

I think both are reasonablely well made. I would definitely recommend the MFJ269 over the MFJ259 just for the extra features provided not only for the wider frequency spread, get the MFJ power supply and buy the rechargeable batteries elsewhere (you can higher power batteries for less money than what MFJ charges at the W*****T store).

That's outstanding John! Congratulations.

I wound up buying an HF9V the other week. The morning after I installed it I hit a VK3 on 40. My report was 5x8. For me, having never worked a single DX outside The States on 40 with a dipole, that was a record. Very impressive verticals those Butternuts.

Regards,
Alan (and, off to the coast again this weekend :-)

Source record: 131392

WA3FET, who teaches in the EE department here, has designed an 80-Meter dipole that uses two conductors in parallel with the dipole which is fed by a quarter-wave matching section. The antenna is a few feet wide and has a SWR of 1.5:1 or less accross the entire band.

Art,

This sounds like the dual of the Beta(?) match as used on some Hygain and M**2 VHF/UHF beams. Clearly mechanically superior, at least below 144 MHz. What feedpoint impedance do you come up with? Hygain and M**2 set theirs up for 200 ohms. Perhaps they do 200 ohms because a 4:1 narrow band balun is a lot easier to come up with than a 1:1. Do you have dimensions for a particular case?

2502. Re: Autek or MFJ ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 14:10:40 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <ar2v8u$lv7$1@knossos.btinternet.com>
Source record: 131390

Here in the UK I have had both for several years. They are expensive enough to make the average Ham stop and fhink. They are sold as sophisticated SWR meters but they are far more useful than that.

I find I use one just as often as I use the other. The MFJ presents data in more detail than the Autek which saves time and labour if further calculations are needed. But the amount of information is the same since they both operate on exactly the same principle. The MFJ has a more sophisticated internal data processor. That's why it costs more.

They both offer a so-called SWR meter range merely as a selling point which in practice is useless because other ranges tell you what you really want to know about impedances.

The MFJ has a much higher frequency range. I am not much interested in the spectrum above 30 MHz. But I have reason to believe accuracy falls off fast at VHF which the Autek doesn't cover. Let's say I'm suspicious. On the other hand the accuracy at VHF is probably good enough for most purposes involved with adjusting Ham antennas.

I use the MFJ mainly in the shack for measuring coils, capacitors, tuners, feedlines and things. It runs off the 50 Hz 240V power supply with a choke balun wound on a ferrite rod in the power lead.

The Autek is used mainly outdoors in the back yard to measure antennas and ground radials etc. The small internal battery doesn't last very long so I use a larger external 9V battery taped to the case. It can still be held in one hand. Or even hanging in mid air on the end of its measuring leads while the user records results. With my sort of usage this is a distinct advantage over the MFJ with its power lead.

Either of these instruments knocks the usual so-called SWR meter into a cocked hat. The best things since sliced bread. (Do you in the USA still eat such mundane stuff as bread, cheese and pickles? Or are you entirely addicted to Big Macs?)

At HF, both instruments are more than accurate enough for amateur needs. Frequency accuracy of the Autek is exceptionally good. But both have the same handicap - inability to distinguish between the +ve and -ve signs of reactance X when measuring R+jX.

Manufacturers' designers have known for years how to overcome this important handicap. But it seems company accountants/marketting experts/shareholders will not put an instrument on the market until they have cleaned up with their existing products.

2503. Re: Broarder bandwidth

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 14:10:41 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <ar2v90$lv7$2@knossos.btinternet.com>
Source record: 131391

The trick is to have two closely over-coupled antennas. Feed one,
overcoupled to the other.

We have the two-humped response of a pair of coupled tuned circuit.

The coupling coefficient has to be large because of the relatively low
antenna Q's.

Antenna Q's are low because of the relatively large radiation resistances in
high-efficiency antennas..

Having put you on the right track can I now leave you to fill in the details
of the final design of a wideband pair of dipoles? Or can we leave it to
the wisdom of the ancient Chinese ?

Trouble is - by the over-riding laws of nature it will be only a one-band
antenna. So nobody will be interested in one band if the only saving is 1 or
2 seconds of twiddling the knobs on the antenna tuner while watching the
so-called SWR meter.

Theoretically the bandwidth can be doubled but with twice the loss. But
nothing ever works according to theory anyway. So sadly let's forget the
whole idea. ;o)

2506. Tri-band vertical and discone on one mast?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 15:27:02 UTC
From: cprstn54zz@att.net
Message-ID: <3dd50f91.2604078@news-server.optonline.net>
Source record: 131395

I want to put a 6m/2m/70cm vertical and a discone on the same steel Radio Shack mast to be mounted on the gable end of my house near the peak of the roof.

The discone fits in the center of the mast. The vertical has its own short extension mast that clamps onto the main mast, and so is offset around 2 inches. It can be positioned to start a reasonable distance above the discone.

1) Assuming I only TX on one of them at a time and use only the vertical for 6m/2m/70cm, will they significantly interefere with each other?

2) What is the minimum distance I should provide between the disc and the lower end of the vertical?

3) Do the discone legs need to be above the peak of my roof? The roof is plywood over wood framing, with asphalt shingles over. The XYL-preferred alternative is to mount the discone so the disk is just above the peak and most of the cone is below.

Hi There,

I currently running an inverted V halfwave dipole on 40m, but I'm trying to improve on it.

My Idea on the improvement is to strap 2 40m inverted V's together and both firing at the same time. I've been told that this works well.

The question I would like to ask is, does anyone else know of anymore configurations I could try to improve on, on 40m. Loops are out of the question as I'm not a Loop fan!!

Cheers for any help...

Maybe I misspoke here. At the time I was using the
Patent Office as a sort of technical overview of ideas.
Then I met the examiner and realised that my original
thoughts of the Patent Office was ridiculous and threw
away many write ups.
My main thoughts with such an antenna feed was that the
military had a need for a frequency agile radiator where
they could code messages with the use of high speed,
high frequency, multi hop messages to hinder interception
of same.
Sorry if I mislead anybody.

some tips from the experts on the best choice for an antenna.

Currently, we're living in a 40'x12' park model RV (the kind
of rv that looks--and lives--like a small mobile home) in a Michigan
resort. Our rv is 1-1/2 stories (it has two bedrooms in lofts
upstairs) with the usual aluminum siding and shingle roof. The lot
itself is approx. 25'x60', with tall trees across the back (25') side.
Obviously, our only practical solution will have to include a roof
mount installation. We already have a (very large) DirecWay 2-way
satellite Internet antenna there, which would make it difficult to use
even a relatively small beam on the roof w/o conflict with the dish.

Obviously, a vertical is probably our most practical solution
(unless someone can suggest an alternative, given the space
constraints--we _can_ anchor the end(s) of a wire antenna to the trees
behind us, but only if we keep the anchors high and within the 25'
width limitation). Our primary questions concern the use of radials
and grounding. With respect to radials, I read on the Butternut site
that mounting in the center of the top of a mobile home obviates their
need and provides an extremely efficient ground plane, in much the
same way that mounting in the center of the roof of a car does so for
a mobile installation. I've been unable to verify this claim in any of
the (limited) resource works I have on hand--can anyone tell me if
it's accurate and, if so, whether it would therefore allow for the
effective use of an antenna such as the Butternut HF-9V coupled to a
TBR-160S 160m add-on (which isn't recommended for use with the
Butternut CBK kit--used to substitute for an efficient ground plane).

Right now my primary concerns are: (1) an efficient antenna
system that will provide coverage of as wide a range of bands as
possible (I'm using an FT-920 which covers 6m-160m) with a reasonably
good swr (i.e., one that can be tuned easily with either the built-in
tuner in the FT-920 or, if necessary, with my external MFJ-969 tuner);
(2) efficient use of space (the antenna _cannot_ extend beyond the
limits of the lot size, and the less space it occupies the better);
(3) reasonable wind resistance (the antenna will be exposed directly
to winds from the SW, S, NW, & N but sheltered from the East) without
extensive guying (space considerations); (4) reasonable cost and ease
of installation (I'm a semi-retired college professor with the
climbing ability of the average horse and don't expect to have any
skilled assistance with the installation); (5) dependability.

My primary questions:

1. How accurate are the statements concerning the efficiency of a mobile home/rv as a part of the ground plane?

2. Should the rv itself be grounded directly (it isn't currently) or will this defeat the effectiveness of the capacitive coupling to the ground itself?

3. What kind of antenna would work the best in this circumstance--other than a vertical are there other, potentially better, solutions?

4. If a vertical is selected, what vertical would you recommend and--if one is available for it--would it be likely to work with a 160m kit?

Any answers, suggestions, or comments would be greatly appreciated, either here or via email.

2512. Re: Broarder bandwidth

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 16:16:01 UTC
From: "Fred Hambrecht Sr." <w4jle@charter.net>
Message-ID: <uta7e4337m4k8b@corp.supernews.com>
Source record: 131400

You should know by now that there are two kinds of folks on newsgroups, the first come seeking/sharing knowledge and the second revel in making any information as obtuse as possible and can prove that no antenna will ever work under the conditions stated.

Forget all the nonsense and write up your antenna, submit it to QST and CQ for publication. Let the ham community decide if it is useful to hams. Forget the experts that demand an antenna must work perfect under all conditions to be called an antenna. We are not commercial broadcasters and can live with less than optimum radiators. I for one would be interested in a wideband 75 meter antenna. It is the only band I really enjoy DXing on and have used cage dipoles and the old Collins spread wire design to enhance bandwidth. I hate messing with a tuner and have used Cam's method of tuning to go from the DX window to the SSB net.

How about some specifics on your approach. Those of us in the first group would appreciate it.

These are messages to spy type folks. The numbers refer to a page,
paragraph, and word number in a pre-agreed on book. It has been going on for
years and most of the transmissions originate in Virginia and beamed toward
Cuba. Care to guess who might be the originator of the messages?

I'm sure there are a lot of messages passing through Al Jazeera too. Makes you wonder if CNN is ever used as a conduit. (This paranoia has got to stop!:-)

The big advantage of using standard SW broadcast bands is that a SW receiver can be purchased cheaply anywhere in the world. No satellite technology required here.

It's funny but when I was learning spanish 30 years ago I used to listen to these same broadcasts. I'd fall asleep at night listening to the monotonous drone of numbers.... "siete, cinco, uno, ocho, cinco..."

2515. Re: apex up, or down, for best DX'ing?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 16:32:07 UTC
From: Larry Higgins <n9dx@attbi.com>
Message-ID: <bk9B9.10325$__1.3779@rwcrnsc51.ops.asp.att.net>
Source record: 131402

More height might indeed be desirable, but this antenna will not, IMHO, "suck ass" on DX. It will certainly perform better than a dipole or a single loop at the same height. The gain will be about 4 or 5 db over a single loop at the same height. Perhaps equally important, loop antennas such as quads or delta loops have excellent side rejection so if an interfering station is at or near 90 degrees to the side the QRM is greatly reduced.

The question of top or bottom feed is not important. The current distribution in the antenna shows maxima at the feedpoint and at the opposite point. This is true regardless of the loop geometry: quad, triangle, circular, or whatever. The current maximum at the feedpoint will be slightly higher than the one at the feedpoint. Therefore feeding the top results in slightly higher gain. Again, this is true regardless of the geometry chosen.

From a mechanical point of view, the apex at the top can be accomplished with a single support for each loop, even with wire loops. With their apexes at the top, multielement antennas can be supported by suspending them beneath a catenary rope.

2516. Re: apex up, or down, for best DX'ing?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 16:42:51 UTC
From: Larry Higgins <n9dx@attbi.com>
Message-ID: <fu9B9.9119$P31.2807@rwcrnsc53>
Source record: 131403

Larry, with your feedpoint at the point you describe, the polarization is mainly vertical but partly horizontal. If your feedpoint was at the center of the triangle's vertical side, you would then have almost entirely vertical polarization and very little horizontal polarization. However, vertical polarization is not desirable for 15 meter DX because ground losses are greater. If you moved your feedpoint to somewhere just to the right of the bottom corner, your results would probably improve, perhaps by a few db. Not a dramatic difference, but when chasing dx every decibel counts!

The five figure groups used in weather reports are not an encryption -- they are a well known universal code which allows you to plot things like isobars, highs, lows, and such very easily. We used to send in weather from our ships, usually about 10 five figure groups, and the information from all vessels in the area, both commercial and military, was compiled into a large weather map. The central weather agency put that map out in the five figure code. I just sent and received

ths stuff -- the ships meteorologist took care of the
coding and encoding.

I need some explanation help here. How can the polarization be partly
vertical and partly horizontal?
I can visualize circular, horizontal, vertical and all points in between
but not a mix.
Can someone explain this in simple terms for me?

RIck:

I think I have the PERFECT solution for you.

I (and now 3 of my friends) have a Cushcraft MA5V vertical. It operates on 10,12,15,17,20 with max SWR under 1.5

And it's only 14.5 feet tall and needs NO RADIALS! It has 4 "stingers" angled down close to the base. Uses coax provided to form a balun so you don't radiate on your feedline. You just have to be patient and careful when you tune each band the first time by adjusting the mini-stinger rods on each band resonator.

We also use it on our 25' RV while camping. It's fabulous.

Have worked tons of DX with 5x7 - 5x9 reports routinely.

One friend ditched his $500 R8 in favor of this baby he loved it so much!

Another friend pulled down his TV antenna (he now has cable) and put up the MA5V. He says the "eyesore" factor is way less.

And it's only $209 at HRO.

If you decide to give it a try, let me know how you like it.

Rudi - WA6RW

Does this work???? I can't see how this would work. If both V's are
identical and fed at the same point and co-existist in the same exact
place, would it be any more effective than a single wire? It seems
like it would be more effective to use one higher quality conductor
with lower losses than use two wires.

Food for thought Andy.
I would think that the rear of the house would
be 'out of bounds' because of the high voltage lines.
On the front of the house you have the conditions
that it must look reasonable and the size of the lot
rules out radials. To my mind that only leaves the
'flagpole ' type but with it being a vertical DIPOLE form
with the feed line being within the pole. This type of radiator
provides a lower angle of radiation compared to the norm
which appears to be one of your needs.

Yep, my vert noise is OVER 2 S-units here.. Only problem is, a
horizontal dipole is kinda rough in an apartment setting. :) Maybe I
should start looking for a house.. Lord knows I spent enough on this
whole rig / MP-1 deal to make the first mortgage payment. :)

I think I'm in pretty rough shape at my QTH, to be honest.. 2 huge
mercury vapor lights, 8 a/c units, and a CATV repeater - right by my
patio.

Hmm. Maybe that has something to do with it. ugh. :)

Not only is he an arrogant "Know It All" but apparently not as educated as
he claims. One of the main points of higher education is to show you how to
write using proper punctuation and grammar. Someone should educate our friend
on the proper use of question marks and quotation marks as well as
proofreading. He gets an "D" on this assignment.

I'm our government could DF the source of the transmissions
from Virginia or anywhere... esp. since its been going on for
so long.
Wonder if they know?

All Hail Bush,

You forgot CBS, ABC, NBC, PBS and any letters of the alphabet left over from the press corps reporting the latest plans gushing from the whitehouse. Who needs code or spies anymore when state secrets are put up in bright lights for all to see?

National security? What a joke. They wanted to move the trial of a notorious security risk because the FBI kept turning their top secret information over to him for review. That's the solution? In times past this security violation would have had heads rolling, now its just eyes rolling and no more penalty for the bozo that left the Xerox running than one gets for jay-walking. At least Anderson consultants knew how, why, and when to turn on the shredder.

West Point, when under attack and being threatened with a sell-out by Benedict Arnold would be a 230 year old royal park now by these standards of security.

30 years ago when I tripped over the doped out sons and daughters of the elite shambling along the street begging for spare change, I wondered where they would eventually end up after they finished spitting on me in uniform. I no longer wonder, they now occupy the three houses of government preaching patriotism.

But I guess this off-topic to spy numbers. To pull it around I would offer that the right wing has no more legitimacy than the eh/cfa/fractal crew.

2529. Re: apex up, or down, for best DX'ing?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-15 20:14:53 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <utaldtq8juki90@corp.supernews.com>
Source record: 131270

When the orientations of the fields don't change over a cycle, the polarization is called linear. And, when polarization is linear and the E field is oriented vertically, it's called vertical polarization; horizontal polarization is when the E field is oriented horizontally. But these are just two very special cases of linear polarization -- the E field can be oriented in any direction (except that it can't have any component in the direction of travel in the far field if the medium is lossless). Describing polarization as having vertical and horizontal components is exactly analagous to describing a tilted line in terms of X and Y, or a location as being so far to the east and so far to the north of another. For example, if the E field is directed at an angle of 45 degrees relative to vertical or horizontal, it's said to have equal vertically and horizontally polarized components. Just like a 45 degree tilted line of length 1 which spans 0.707 units in the X direction and 0.707 units in the Y direction, a 45 degree tilted field of 1 V/m can be said to be composed of 0.707 V/m of horizontal polarized field and 0.707 V/m of vertically polarized field -- if you added those vertical and horizontal components together in the same place, you'd end up with the tilted field.

If you're curious about a particular antenna, you can download the free EZNEC demo from http://eznec.com. In the main window in the Plot menu, you can select "2D Fields to Plot", then "Vert, Horiz, Total". Then, EZNEC will show you the vertical and horizontal components separately in the 2D plot. You'll learn some interesting things, such as the fact that the radiation from a dipole is purely horizontal broadside to the antenna, purely verical from the ends, and a combination of the two in every other direction.

Rick,
The first thing is to always take the manufactuor's claims
with a large dose of the salt of your choice. Having said that,
there are a few other things to remember.
Any antenna works 'better' with a good ground under it,
verticals,
horizontally polarized, what ever. Even the so-called 'no-ground'
verticals.
Your motor home should be grounded no matter if you use it for
part of your antenna system or not. That's just common sense for
safety. If yours is like most motor homes, the metal 'skin' isn't
necessarily electrically connected. Motor home builders are more
conserned about weather proofing than electrical continuity, so
this
panel may not be connected electrically to that panel. If you put
a
vertical on top of your motor home, you might want to give some
thought to bonding the different metal sheets together. You might
also
think about running ground wires to the corners of your home, then
to
radials in/on the ground. It isn't very apparent by listening,
but they
do help. It doesn't decrease the coupling with ground
(capcitive), it
increases it, which is good.
You have a number of other choices besides a vertical antenna.
The
size of your lot is such that there ought to be some way of
putting up
a doublet of some kind. It might take a little 'creative'
thinking,
but I'll bet it can be done. It should be somewhere close to a
1/2 wave
for the lowest band you plan on using (if possible). Feeding it
with
ladder-line through a tuner should put you on almost all bands.
Maybe
not with the best signal in the world, but workable. Trees make
good
antenna supports. Deviating from the 'classic' design of the
various
kinds of antennas is allowed. In other words, what ever works,
works.

There really isn't a ~"best"~ antenna, but there are antennas that work well given the conditions you have. About the only way of telling
which is 'best' for your situation is to try it ans see.
I won't say what I think the best vertical is because first, I'm not
much of a vertical fan. And most can be made to work well with enough
effort. Any multiband vertical is going to have bandwidth limitations,
and if you can live within those limits, then you should do fine. In a
very broad generalization (which means there's always going to be exceptions),
is that the taller the vertical, the better, even with loading for the lower
bands.
Good luck.
'Doc

Jim's design sounds like it might be based on a technique patented some years ago by Gary Breed, K9AY, number 5,489,914. (The patent is no longer in force due to lack of renewal, so the method is in the public domain.)

I would rather not getting into all the details and then leave
myself open to ridicule again. Obviously impedance levels would
vary depending on the coupled antenna but the concept can easily
be verified by adding such a feed method of any sort of dimensions
and then scanning the frequencies.
One time I stuck some duck tape on the center of a vertical upon
which I stuck some aluminium tape.Connected the alum tape delta
feed wise and just thrust the feed line without care within the
radiator. It worked just great on many bands but then antennas
want to work for you don't they?

Doc,
When you say ground your motor home--- if you are in a camp ground, would a copper braided line of sufficient length with 2 alligator clips, one clipped on to, say the bumper or frame, and the other possibly to the pad where the hookup is, suffice? How about the 3 prong plug of your hookup cord isn't that enough?
I have in the past used a Hygain 18AVQ vertical with no radials on 80 to 10 mtrs in a camp ground, ground mounted by just driving a pipe into the ground and putting it up with good success.

Would not a set of parallelled dipoles, one cut somewhere near the high end of the band, and the other cut for near the low end of the band (say on 75 meters) perform this function? If they were mounted on nearly the same plane but far enough separated that they don't directly interact the directivity and pattern shouldn't change much.
Seems the main problem would be exactly where (what frequencies) to cut them for so that they provided the correct amount of opposite reactance across most of the band.

This scheme was explored in Ham Radio mag in the early 80's but not many details were forthcoming. What's your opinion, Roy?

I had a two band quad beam in AZ that had a driven element resonant
on 16Mhz with a reflector for 17m and a director for 20m. It output
its signal in the opposite direction from what a visual inspection
might indicate.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <utas51h0u9ms46@corp.supernews.com>
Source record: 131283

Egad. No, I wasn't speaking of coax. The issue came up -- I assumed -- because I said I couldn't figure out how crossed 40 meter dipoles would fit on a 100 X 20 foot lot (with a possible additional 30 feet somewhere). It has nothing to do with coax. Rather than giving nospam a fish by telling her how long a 1/4 wave was on 40 meters, I tried to teach her to fish by telling her how to calculate it, roughly, using approximations and simple arithmetic.

I see that my fishing lesson was a complete failure. So, for those who didn't get it, I suggest looking it up. I'm sure that somewhere on the Internet you can find what a quarter wavelength is at 40 meters, without having to apply any thought or elementary arithmetic. But watch out for automobile and insurance salesmen -- you're their rightful prey.

Hi Dave,

It will work, but you'll lose any directivity, since the dipoles are pointing at all points on the compass. I've used the same idea with a CW and a Phone antenna for 40m. Fed with the same coax. Do you need a Balun? seems like an unnecessary part to me.

Good luck and good DX,

Bill, W4WNT

Take your inverted V and turn it into a top fed L. Make one half horizontal
and the other half vertical. You can think of it as an upside down vertical
or both a horizontal and vertical antenna. Either way you get low takeoff,
omni directional coverage. For an article on all band top fed L antennas
see http://www.cebik.com/ltv.html and http://www.cebik.com/gup/gup25.html

I didn't do a proper job of qualifying what I said. I was referring only to feedpoint matching methods. There are certainly other ways to broadband an antenna, such as using parallel or spread wires, either the same length to form a cage or cone of large effective diameter, or with slightly different lengths. The method Gary Breed came up with was to put another wire or wires parallel and very close to the dipole, but with no direct connection. This can be used to either increase the bandwidth or to add the capability to work other bands.

Of course, you know how I'd figure out how to cut the wires -- I'd use EZNEC. But then I'm highly prejudiced.

Subject antenna sold for US$17.05 (approx. Cdn$26.85). Could have been picked up at a Radio Shack 'Clearance Sale' for about Cdn$5 anytime within the past year or two.

The Nixie Display Tubes (previous thread) that I had donated to a "Collector" in the early 1980s recently sold for US$32.05 ! I had bought them for maybe 0.25 each.

I am sooooo going to clean out my basement and attic this autumn ! Plenty of very nice antenna and other such 'junk'. Should be able to pay off my car at these sorts of e-bay prices.

Apologies for OT - I'm just flabbergasted at the e-bay prices. Good money for old rope.

No. EZNEC, with its NEC-2 calculating engine, is better at dealing with close spaced parallel wires than MININEC-based ELNEC. With ELNEC, you need a lot of segments for parallel wires, since the segment length shouldn't be more than about twice the wire spacing. (And with the original MININEC, you can't get decent results at all with close spaced parallel wires.) Much longer segments are tolerable with EZNEC. The only caution when using any NEC based program for close spaced parallel wires is that the segment junctions should be directly across from each other. This is easily assured by breaking the longer wire (if they're different lengths) into three wires, with the central one being aligned with the shorter wire, and having the same length and number of segments. That is, you begin with two identical parallel wires, then add wires to the ends of one of them as necessary. Variations of this method can be used depending on how the wires are aligned with each other.

David,
I don't know if the way you described would be
'enough', or not, but I don't see how it could hurt
anything. I was under the impression that the motor
home was sort of semi-permanently parked, or at least
in the one place for an extended time. If so, then
as long as you were careful of how you did it, I don't
see why anyone would object to laying out a few radial.
A 25 by 60 foot 'pad' is sort of large for the average
over-night camp site, isn't it?
As to the '18AVQ' vertical, I wish I had the one I
used to have 30 some years ago! I think I had one or
two short ground rods and the pipe it was mounted on.
It did very well with just that. Of course that was
during a 'cycle' when a wet noodle would work too!

Hi Art,

I added my pennyworth only from the subject heading. I have read very little of the thread and I have no idea of the construction of the antenna you propose or of what adjustments you suggest. And I still havn't. ;o)

So my square-one comments about double-humped bandpass circuits (see Terman et al) were unrelated to what you have in mind. I'm just an innocent bystander looking the other way caught up in the crossfire.

But from my previous experience of your writings there has to be something sensible and useful in what you are now saying but which I havn't read on this occasion.

I would have thought Eznec or one of its derivatives would have solved your problem of how to convince people that your ideas work or, of course, don't work. The only way to convince is to present some NUMBERS.

One or two of my own programs only serve to illustrate, on the most simple of antennas, how very insensitive bandwidth is to whatever means are attempted to broaden it.

Any small benefits accruing from broader bandwidth are mostly outweighed by the trouble and strife needed to obtain it.

What's more effective than 24 gauge nichrome antenna wire?

And why does everybody conveniently forget that the transmission line has just as much an effect on SYSTEM bandwidth as does the antenna? It adds hell of a lot of L and C but neglgible R. For the same reasons a tuner also sharpens bandwidth. If bandwidth is so important why don't you guys argue about these other system components.

Come on you Guru's, what are you waiting for?

Reg, G4FGQ

Hmmm. At:

http://www.cebik.com/amod/amod56.html

LB sez:

"There are, then, antenna wire geometries for which MININEC is the
preferred modeling core, especially if that core has been adjusted to
overcome past known weaknesses. This is the case with Antenna Model,
although if VHF and upward frequencies are not used, ELNEC will handle
close-spaced wires quite well and if no close-spaced geometries are
involved, AO will handle VHF and UHF frequencies well. See column #50
for further specific comparisons among MININEC cores."

Elsewhere, he gives you credit for having a good close-spaced wire
correction.

I guess I need to some more indepth reading.

After spending a great deal of time working on my BSEE and my MSEE, what I have learned about higher education is this, students are for proof reading manuscripts and working like dogs so the enlighten ones can get "Published". At the very least, they are around so the enlighten ones can look down upon their miserable stupid students and gloat about how they "helped invent" some piece of techology at Bell Labs or something important place during their glory days.

I have also learned from many hours of research that most "Published" works is just a rewording of the same old topics to appear to be original.

By the way great move to add some extra credibility by looking like an "seasoned" ham with the 1x3 call sign.....when you were actually first licensed sometime in the after 1969 as WB8EIY. I ought to know as my WB8 call was issued in 1969 and it is older than yours. I would bet you used to work at OSU's Electrosceince Lab.

The page you refer to illustrates how MININEC can produce better results when close spaced parallel wires have very different diameters, and I agree with LB's findings. (I haven't done a rigorous analysis, but suspect that the problem lies with the connection between them, and that NEC-2 would do fine if the wires aren't connected, as in Gary Breed's scheme.) For wires of similar diameter, however, NEC-2 based programs will give at least as good results with fewer segments than MININEC based programs.

The original MININEC code would give wildly bad answers if wires were even moderately close together. I fixed this in ELNEC, but ELNEC still needs segments to be no longer than about twice the wire spacing (actually, you can usually push it to about two and a half times). I think this is pretty fundamental to MININEC, but maybe other developers have found a way to improve on it. NEC-2 tolerates much longer segments for parallel wires.

Hi,

Excepting your respect, this argument is not sufficient to say your
antenna is better than another.
With the propagation conditions that are decreasing due to the lower
solar activity after the 2000-2002 peak, it is quite normal you
experiment better results on the lower bands for a few months or so.

My nearest friend uses a Cushcraft R7000 placed 5m high at the end of
his garden 100m away from all buildings and has confirmed over 280
DXCC since 1999, whatever the band.
However last week we both were unable to work R1ANC. We heard him but
he cannot heard us located 15000 km away on 15m (we are in south ON).
If it was on 40m beleive me my friend 'd have his QSO confirmed !

Personally I am well unable to make the difference between
performances of a Cuschraft, Butternut or High-gain models, and this
is therefore I use a dipole !

Hi,

There is also this alternative, the buddipole, a versatile dipole you
can setup like a vertical thanks to its rotatable axis.
Good construction, accessible price, etc
Check on http://www.buddipole.com/

There are several ant. of this kinf on the market.
See maybe on www.eham.net too.

Larry, N3CCW wrote:
"Can you elaborate?"

Displacement current happens in an insulator. Electrons don`t ordinarily migrate in high volume through insulators or free space as they might through a conductor. In a void or in an insulator, like charges repel and unlike charges attract. If there is a complete circuit containing a capacitor, current can circulate via displacement current across the conduction gap of the capacitor.

Antennas have limited lengths but current flows through them because displacement current provides a place for current to continue despite a wire which ends.

Maxwell speculated displacement current produces a magnetic field the same as a conduction current does. He has been proved right. This is the secret of radiation, as Maxwell suspected.

A changing potential difference produces a changing electric field, and a changing electric field produces a changing magnetic field, which produces a changing electric field, etc., ad infinitum.

Best regards, Richard Harrison, KB5WZI

Without further clarification, it is difficult to make a recommendation. Are you interested in receiving all local stations? Select stations in fringe regions? What is the volume of space available? What metallic items are close by? Etc. Etc.

Best of luck.

Evan

Source record: 131307

With the double Hamstick dipole you will be unable to get the SWR down to a manageable level for the greater part of any band (i.e. you will have very limited bandwidth). The performance will be poorer than a mobile antenna on a car in most instances. But, it is an antenna, and it will radiate a small portion of the power. An antenna tuner is mandatory.

Best of luck and 73s,

Evan

Right now, the only grounding for the rv (it's a park model
trailer--essentially a small mobile home with 1-1/2 floors--not a
motor home, btw) is through the electrical hookup (50A grounded
circuit). I _do_ intend to drive a standard copper grounding rod into
the ground and fasten it to one of the tie downs provided with the rv,
which are connected directly to the chassis (and are currently not
connected to the ground as the rv is not on a concrete slab).

Incidently, the skin _is_ electrically connected on our rv--at
least to the point that there is no significant resistance measurable
between any two points on the rv (I connected wires to various points
on the rv and measured for resistance).

> You might also think about running ground wires to the corners
>of your home, then to radials in/on the ground. It isn't very
>apparent by listening, but they do help. It doesn't decrease
>the coupling with ground (capcitive), it increases it, which is
>good.

Can't do it (I wish I could, laying out radials would solve a
lot of antenna problems). With the exception of a single grounding
post or antenna mount of small diameter, nothing is permitted to be
buried by the resort rules--and neither can the radial wires be left
on the surface of the site. That's one of the reasons I've been
looking for no-radial options.

> You have a number of other choices besides a vertical antenna.

I've been looking at a few--in particular, either the
Butternut HF5B "Butterfly Beam" or the Cushcraft MA5B beam. Both are
small enough to mount directly over the center of my roof (where they
would clear the DirecWay dish) on relatively short tripods, and their
turning radius would keep them over my lot. Using one of those in
conjunction with a vertical or dipole for the bands it doesn't cover
would, obviously, be a step up from a vertical--assuming I don't run

into the same ground plane problem there, of course.

I've also looked at a number of pre-assembled dipoles--including the Yaesu YA-30 which is only 83' long and claims to be pre-tuned for all bands (1.8-30 MHz) with a max swr of 1.9:1. Obviously, the antenna would need to be used in some form of "V" configuration, since I don't have 83' of space in any direction (including diagonally) on my lot. Because of the layout of the lot, an inverted "v" would be unworkable (the ends would have to go to the rv front & the center to a tree behind it--which would be far too narrow a spread for the "v"--in addition to which, the roof of the rv is peaked and that would put them at the low points), and I've never seen any information on a standard (non-inverted) "v" to determine if it could work that way with the center at the top of the roof and the legs connected to two trees behind the rv.

Adding to the already frustrating situation is the fact that, I'm partially handicapped (knee and respiration) and thus heavy roof work isn't an option--nor is having other local hams help out, since the resort (for liability reasons) won't let anyone not a member do any work on a site unless he or she is a licensed contractor doing the work commercially (and thus insured by his/her own firm against injury). I can get away with having my 18 year old son help (family membership), but he knows nothing about ham radio (he's a computer hobbyist <sigh>) or about installing antennas and will have to be "stepped" through the entire procedure.

>The size of your lot is such that there ought to be some way of
>putting up a doublet of some kind. It might take a little 'creative'
>thinking, but I'll bet it can be done. It should be somewhere close
>to a 1/2 wave for the lowest band you plan on using (if possible).

Let's see--1/2 wave at 160m . . . Ouch! :-(

>Feeding it with ladder-line through a tuner should put you on almost
>all bands. Maybe not with the best signal in the world, but workable.

Tuners I'm used to. At my former location, I used an 18' flagpole for a vertical (tuning it--believe it or not--with the built-in tuner in my FT-920) and managed to hit both WAS and DXCC using the absurd setup! Unfortunately, I can't do that here as it would require too much digging (I set the flagpole in an insulated base in 4' of concrete with the ground side of the coax connected to a 4' copper grounding post mounted directly beside it) and would be far too close to the rv (and would thus be affected by the metal siding).

>Trees make good antenna supports. Deviating from the 'classic'
>design of the various kinds of antennas is allowed. In other words,
>what ever works, works.

Here, unfortunately, is where I'm the weakest. I have a pretty decent understanding of circuit design and both digital and analog electronics, but when it comes to propagation & antennas, my knowledge

is pretty much limited to the areas I studied for my Extra (and, before someone points out the obvious, yes I know that's insufficient--but few of us are "balanced" in all areas of communications). Beyond the basics, I'm not familiar enough with antenna design to know how much "deviation" _can_ be used before the installation stops being a tuned antenna and becomes a random wire instead! In particular, I'm weak in areas dealing with ground coupling, antenna shape (i.e., is an upright "v" as effective as an inverted-"v"), or the effects of such objects as a metal clad (wooden roofed) rv in close proximity to an antenna system. Obviously, I can do the math to determine the appropriate length for an antenna, etc., but as far as actually determining the best type of antenna--or how to install it under these circumstances--I rather rapidly reach my own limits of knowledge.

Incidently, you mention in another response that the size lot I'm on is large for a campground. It is for an "overnight" type campground--but it's relatively narrow for a semi-residental resort such as this one. Several of the lots here are 10' wider (which would make antenna selection MUCH easier--but given their location wouldn't be worth the trade-off). Our rv is a 40'x12' park model with two bedrooms upstairs in the lofts and one downstairs--the largest an rv can be built (in Michigan--Florida allows a few feet more) and still be classified as an rv instead of a mobile home, and thus it occupies a good portion of that lot (we have about 10' from our front door to the edge of the lot and about 15' behind us). Effectively, anything we put up has to either mount to the rv itself or from the rv to the trees 10' behind the rv--there aren't a lot of other options, including ground mounting a vertical, given the layout of the lot.

Thanks for the help & suggestions--if you, or anyone else, happen to be familiar with any of the alternatives I mentioned above, feedback would definitely be appreciated.

What you say it true for 75m. However, a double hamstick dipole makes a
pretty good antenna for frequencies above 14 MHz. The fact that it is
rotatable gives it the advantage over a full size fixed dipole in some
directions.

On Fri, 15 Nov 2002 11:05:15 -0500, Rick Adams <ke8hh@qsl.net> wrote:

[snip]
|
| Obviously, a vertical is probably our most practical solution
|(unless someone can suggest an alternative, given the space
|constraints--we _can_ anchor the end(s) of a wire antenna to the trees
|behind us, but only if we keep the anchors high and within the 25'
|width limitation). Our primary questions concern the use of radials
|and grounding. With respect to radials, I read on the Butternut site
|that mounting in the center of the top of a mobile home obviates their
|need and provides an extremely efficient ground plane, in much the
|same way that mounting in the center of the roof of a car does so for
|a mobile installation. I've been unable to verify this claim in any of
|the (limited) resource works I have on hand--can anyone tell me if
|it's accurate and, if so, whether it would therefore allow for the
|effective use of an antenna such as the Butternut HF-9V coupled to a
|TBR-160S 160m add-on (which isn't recommended for use with the
|Butternut CBK kit--used to substitute for an efficient ground plane).
|
| Right now my primary concerns are: (1) an efficient antenna
|system that will provide coverage of as wide a range of bands as
|possible (I'm using an FT-920 which covers 6m-160m) with a reasonably
|good swr (i.e., one that can be tuned easily with either the built-in
|tuner in the FT-920 or, if necessary, with my external MFJ-969 tuner);
|(2) efficient use of space (the antenna _cannot_ extend beyond the
|limits of the lot size, and the less space it occupies the better);
|(3) reasonable wind resistance (the antenna will be exposed directly
|to winds from the SW, S, NW, & N but sheltered from the East) without
|extensive guying (space considerations); (4) reasonable cost and ease
|of installation (I'm a semi-retired college professor with the
|climbing ability of the average horse and don't expect to have any
|skilled assistance with the installation); (5) dependability.

You will not find an "efficient" system that works all of the bands.
The best you can do is a workable system.
|
| My primary questions:
|
| 1. How accurate are the statements concerning the efficiency
|of a mobile home/rv as a part of the ground plane?

Probably manufacturer's hyperbole.
|
| 2. Should the rv itself be grounded directly (it isn't

|currently) or will this defeat the effectiveness of the capacitive
|coupling to the ground itself?

Regardless of what antenna you put up the RV should be grounded. From the other posts in the thread I believe it is as far as safety goes. You mention elsewhere the tie down hard points on the RV. Aren't these in use with ground anchors and straps now?
|
| 3. What kind of antenna would work the best in this
|circumstance--other than a vertical are there other, potentially
|better, solutions?

A vertical on the roof would probably do okay on say 10-12-15-17-20 where it could be nearly full-size. As more loading is used to resonate it on the lower frequencies, it will become less efficient and the BW will narrow. OTOH, on 10-12-15-17-20 and maybe 40 you could have a full or nearly full-sized dipole that would fit in you space. The horizontal polarization on those bands would be preferred.
|
| 4. If a vertical is selected, what vertical would you
|recommend and--if one is available for it--would it be likely to work
|with a 160m kit?

I have no experience with the commercial verticals. As a practical matter, I believe that you should forget that the 160 band exists.
|

You don't say how high the trees are. It seems that the park rules would permit some type of mast (they allow the vertical right?). What if you ground mounted a tv style push-up mast at the end of the rv opposite the trees and ran a dipole from there to the trees. You could make the wire longer that the distance between supports and dangle the end down if necessary.

Feed this with ladderline if you prefer or build some traps. Despite what the ladderline proponents say, if the wire is shorter than about 3/8 wavelength you will have a problem, so figure this into you available length situation.

Traps will allow resonance on several bands, albeit with restricted BW and some loss, but what the heck any vertical you put up has the same limitations.

I read his article in RF Design magazine years ago and I think I still have it somewhere (I subscribed until I retired). I believe paralleling dipoles cut for each end of a band to provide the broadbanding compensating network for each other might work a bit differently. I'm sure you could clearly explain the comparison while I'd stumble around trying. IIRC His scheme was a matter of induced currents onto the free resonant wire from the driven wire.

> EZNEC. But then I'm highly prejudiced.

Here's where I would enjoy antenna modeling. I suppose I should get started and do some of it if I'm ever going to.

I think many if not most of us hams have successfully used antennas that we really wouldn't want to know too much about. :-) Might be a bit difficult to explain why they seemed to work so well!

|I know I am feeling a bit down but I will be better tomorrow.

Art, I certainly hope so. You are being quite unfair in your critique of the "state-of-the-amateur-art."

You accuse others of knee-jerk responses that immediately dismiss new ideas, and "follow the books", but for the most part, the "books" have been vetted repeatedly and are our "best guess" at how things work.

Believe me, I have tried on several occasions to model designs that you have offered. While it is likely that I didn't understand what you were saying and the models didn't represent what you had in mind, I don't believe it is my shortcoming. I have tried with your "loop-fed" (my description) dipole and with the configuration you have proposed in this thread (Witness my query about which is better, mininec or nec-2 for modeling close-spaced wires) and for the life of me, I cannot achieve results as you describe.

As I have offered to do in the past, if you can provide a succinct description of your "Off-center-capacitive-coupled-multi-band-feed system", I will gladly model it and provide the results to the group for critique of both my modeling technique and your design.

2578. Reflected power

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-16 17:39:30 UTC
From: jder8745@aol.com
Message-ID: <20021116123930.21327.00000039@mb-cl.aol.com>
Source record: 131317

Howdy, Hammers

The whole idea of forward and reflected power in the steady state is only a mathematical way to look at things.

If the line is lossless, ALL the power going into the sending (transmitter) end of the transmission line goes to the load (antenna) end and is partially radiated and partially converted to heat by losses in the antenna.

By playing like there is a forward component and a reflected component it makes the arithmetic easier.

It's like the rotating magnetic fields in a single phase motor. There is only a polarity reversing field which does not rotate but this can be thought of as two fields rotating in opposite directions. The motor will not start by itself, but if you give it a spin in EITHER direction it will continue to run in that direction.

The only reason I am mentioning the motor s that it shows how we often use mathematical equivalences for the real world happenings to make the arithmetic easier.

And that’s all I have to say about that!

Consider the "GAP Titan DX". Easy to assemble, covers 80 thru 10 meters and NO tuning.

I put one up on a 5' pipe in my lawn and it works very well.

This antenna is available from AES, at least that is where I bought mine from.

Check out this antenna on the GAP web site.

Before I bought mine I checked out several and I feel I chose wisely for the price and no tuning required on assembly.

True...A "hamstick" is a commercial trade name of an antenna, not the
real name. I've got a funny feeling if you would have asked him what a
"helically wound" short vertical was, he would have probably known.
I've never checked, but I've got a good hunch if you read the whole
ARRL antenna handbook from front to back, you would most likely not
see the word "hamstick" mentioned one time.

Playing like there is a forward component and a reflected component
also causes ghosting in TV systems and echos in telephone lines. So
it seems that the more we play like reality, the closer we get to
reality.

If the fields are completely confined inside the tube and if
a load exists, it will act like a transmission line. It is like
running 1/2WL of low loss coax between phased verticals.

With respect to your "electrostatically shielded loop" model, just
model the outer conductor of the coax, which is where the antenna
currents are. The inside only carries transmission line currents,
which aren't seen outside. The "shielding" isn't really shielding at
all, it IS the antenna. I don't think that will help you much with
your antenna embedded in a high-K dielectric.

Cheers,
Tom

When being used to test the larger 160m and 80m antennas on their fundamental frequencies, both meters suffer from interference picked up on the antennas from powerful, local, MF AM broadcasters.

Meter readings become erratic. The internal oscillators have too low a level.

Why would you help a thief out? Why would you help out a dishonest
person ?
Why would you help out a liar? Why would you help out a fool?
In the main, experimentation IS dead on this side of the pond but my
comments do not refer to everybody. I enjoy this hobby and the people
I meet if and when I get on the air, which is not often, so I
certainly would not paint everybody with the same brush.
At the same time I see so many questions that can be solved by the
inquisitive
in an hour or so with a piece of wire in the old days and I see so
many
looking for faults but I still hang around because I like the hobby. I
am not an illiterate,thief,dishonest,ignorant or a liar as some would
paint me .
I would say that I do not communicate very well, but burning at the
stake is a bit too harsh for those who possibly are mentally ill. By
the way the record is clear that all has been disclosed and shared
with amateurs, those who are interested in pursuing can do so quite
easily tho probably not as easily as criticising or jeering. Yes,
ofcourse, I am the one who is being unfair, everybody else are such

nice angels.

Good for you.

I have also noted ghosting in my TV set at home. But it was always caused by two different signals reaching the antenna out of phase.

I can rarely remember ever seeing such a phenomenon whilst viewing from the cable.

Except: There is a strong ch 2 station locally. I have seen it cause a ghost while l I am watching cable channel 2. But of course these are two different programs.

I don't think this is what we are talking about, re: forward and reflected waves.

The telephone line echoes aren't a steady state phenomenon but a transient one.

(I can't believe I used the word "phenomenon" twice! There must be a CW shortcut for it.)

Reg,

When using the MFJ on my 75M loop, I get an AM reading, PM readings, and evening readings. My Kenwood power meter says the SWR is 1.2:1 at 3800. Worst case with the MFJ is at night, when it gives me readings of about 5:1 across the whole band. I suspect that in addition to BC stations, and I am broadside to New York City transmitters 15-30 miles away, it may be getting confused by strong 75 meter signals. Nevertheless, I am looking at building a 3 MHz HPF.

I did find the thing quite useful in chasing down a problem with my 2m beam: turned out to be a loose UHF connector that is part of the gamma match.

Just try your local hardware store if the discount places don't have it.
(Lexan) Around here any windows in storm doors have to be made of Lexan.
I picked up some small scrap pieces from their cutter and purchased a piece
3' X 8" X 1/4 inch thick. The stuff is expensive, but strong. I use 3 X 5
inch pieces as center insulators for my 75 meter slopers. They also hold the
baluns and support the coax.

As I bought a piece that was left over they gave me a good price and quite a
hand full of smaller pieces.

If the line is lossless, reflects half the power and we have a good match/line tuner at the rig, and the line is 2 wavelengths long, then: with 100 watts out of the transmitter, 100 watts reaches the antenna BUT, 50 watts is reflected back to the transmitter where it is reflected back in phase with the outgoing power (and is in phase, but two complete cycles behind, so we now have 150 watts going forward. 150 watts gets tot he antenna and 75 watts is reflected back to the transmitter. where we now have 100 + 75, or 175 watts forward. This cycle will repeat until we have 200 watts to the antenna with 100 watts radiated and 100 watts from the transmitter itself.

The thing to remember is that each reflection will be however many cycles behind the first with each sucessive cycle being farther displaced but in phase. (you could say they are out of phase by multiples of 360 degrees.

In voice this is usually not a problem and not likely to be one on CW, but for data and TV it can be a big problem. Ghosts on TV with invalid checksums and other maladies with data.

Hi from a cable guy,
One of the telltale signs in cable troubleshooting of a shield break or missing/damaged termination is ghosting on the low-VHF channels for the subscribers on that particular distribution line. In such case, it is due to reflections of the actual signal.
The 'taps' used are typically directional couplers and will offer in the range of 20db of rejection to backwards travelling signals. As a result, all the normal, minor reflections are way down. But in the case stated there is very little return loss at the fault and the attenuation of the cable for the bounced signal is pretty low at low-VHF...hence it may be visible there and not on the higher channels.

It takes a really long cable to produce an obvious ghost on a TV. The width of the screen is 63.5 us (NTSC standard), and the delay in a coax cable with solid dielectric is about 1.5 ns per foot. So for a reflection to appear, say, 5% of the screen width to the right of an object, the delay would have to be 0.05 * 63.5 us = 3.18 us = 3180 ns. The signal would have to travel through over 2000 feet of cable for this delay, or a round trip in 1000 feet. With the cable used for typical TV applications, the attenuation would be so great in this length of cable that you'd never see the reflection. The ghosts you see on your TV are invariably from the signal arriving at your antenna via multiple paths of different lengths.

Actually, a line-caused echo can sometimes be seen on a TV monitor when both the source and load are improperly terminated. With standard TV quality equipment, you can see echos with delays on the order of 200 ns, which requires a cable length of only 67 feet or so. This looks like a little extra "edge" to an object, sometimes followed by a little ringing, and is often not noticeable except to a critical eye. I've never seen it on a broadcast TV set, but have seen it on closed circuit TV systems when the monitor termination switch was left open and the source impedance didn't match the cable. You'd be able to see echos of shorter duration on higher resolution systems. Like other transmission line phenomena, it can be completely explained in terms of forward and reflected voltage and current waves without having to invoke the concept of power bouncing around on the line.

Rick,
You know the old story, I guess I assumed too much about
your situation. So, lets look at this from another angle.
How do you feel about a mobile antenna(s) mounted on your RV?
It/they wouldn't be the 'best' antenna(s) by any means, but
that's one solution that will get you on the air. The 'catch'
would be 160 meters. That isn't going to be 'easy', but it's
certainly 'doable'. The easiest way with a mobile antenna is
to throw money at it, use one of the 'screw-driver' antennas,
since that would eliminate changing taps on a coil. Put it
on a hinged base, and lay it down when you move the RV. The
RV would provide at least as much 'ground' as a car or truck,
and there are a number of them on 160 meters too. Or, how about
a 'cluster' of 'Hamstick' antennas? Probably not 'better', but
much cheaper than the 'screw-driver'. (An RF candelabra(?))
'Doc

Roy,
Consider that "5% of screen width" even on a 21" TV is about an inch.
Paying viewers get pretty perturbed at a whole lot less than that and
may not even perceive a 1/4" colored fringe to be a ghost. That 1/4"
can be pretty smeary and nasty looking, though.
But even sticking with the 1000 foot return signal, thats only about
5.4db with typical cable at 54 MHz. That, plus maybe 20db of
directional coupler isolation, puts the bounced signal only 25 db down
from the desired signal. This, of course, is assuming a situation like
an unterminated or damaged line that may have a return loss of darn near
zero.
Thats plenty visible on an analog signal and can wreak havoc on a
digital or data signal.

[snip]

Heh, heh... Cecil, "there you go again"!

TV ghosts and echos on telephone lines are signal "dispersions" [a.k.a
intersymbol interference] and are
actually caused by group delay distortions [i.e. variations in group delay
from an absolute flat transport
delay] in a forward transmission path not from "reflections".

In the *steady state* on an unmatched transmission line system there is no
forward and reflected energy
sloshing about longitudinally from end to end of the transmission line.
Rather there is only a transmitted
energy that flows continuously toward, and is dissipatd in, the resitive
part of the load impedance. On
such a transmission line there is however a sloshing of energy back and
forth differentially [i.e. from
side to side or transversally rather than longitudinally.] between the
electric and magnetic fields of the transmission
lines' distributed capacitance and inductance.

In the transient period leading up to the full *charging* of the
transmission line there is indeed energy
reflected back and forth longitudinally, but this end-to-end reflection of
energy ceases after a *few*
transmission line length related time constants have passed as the line
settles into its' regime of transmitting
a steady state power down the line while simultaneously *storing* a finite
amount of energy sloshing back

and forth transversally along its' length in its' then fully charged
distributed electric and magnetic fields as
supported by the boundaries of its' distributed inductance and capacitance.

A much better example of reflections than TV ghosts should be drawn from
systems operated in a more
transient regime rather than in such a nearly steady state regime. A better
example of individual reflected
wave packets would be that of a system operated in a highly transient mode
like a pulsed radar system,
where the system never comes into steady state equilibrium, but where each
echoed pulse is received
individually before another is transmitted.

However, that being said, it is perfectly feasible to obtain the same
results as a pulsed radar using
continous wave techniques. Indeed this is how some synthetic aperature
radar systems work, and so too
do other such techniques such as used in seismic exploration, echo
cancellation in modem systems, etc...
where the time delay between the source and load are well within a the time
period of a single cycle of
the highest wavelengths in use.

A slavish insistence upon a *strained* visualization viewpoint that insists
that all such phenomena must be
described by a Copernican-like model of reflections and echos that is more
complicated than necessary,
even for rigorous engineering design, and which as well stresses the
credulity of both amateur practicioners
and many professionals, and which is so arcane as to require its' proponents
to require *true-believer-like*
interpertations of calculated quantities as *pseudo-powers* is, in my
humble opinion, a somewhat crippled
viewpoint of reflection mechanics. Simplest is best! Why make things more
complicated than necessary?

Any viable and believeable viewpoint of reflection mechanics should be
consistent and work for all dynamic
reflection regimes from direct current [DC] maximum power matching to SHF
pulsed radar systems. There
should be no *magic* frequencies above which one view is valid and below
which another is valid.

Direct current or DC transmission is nothing more than AC operated a
frequency of zero Hz. The models
of reflection mechanics should be consistent from f = 0 Hz all the way to
"daylight" f = oo. DC power
matching *is* the same as steady stated AC power matching, period, end of
story.

Simple calculations involving nothing more than volts and amperes are sufficient to rigorously engineer all
such systems and there is simply no need, other than mathematical convenience, to introduce superflous
auxilliary quantities such as the so-called forward and reflected power.

A theory and/or visualization of so-called reflection dynamics should be consistent and should
result in the same experimentally observed quantitative results for both transient and steady state phenomena
and for all such regimes in the continuum between the transient and steady state.

O.K. so now let me be a bit more specific. When merging a loop with a
dipole radiator where part of the loop rests INSIDE of the dipole,
that within the
dipole takes on the role of a low loss transmission line which means
that I am
conserving energy by not radiating in an UNDESIRED direction tho I may
be creating a loss because of the impedance mismatch of the circuit
within the dipole.
Did I go astray from what you was meaning?
I am testing such an arrangement and want to be sure before hand that
the above
is what I should expect which is also my thinking.
Thanks
Art

I didn't say all ghosting was caused by reflections. But you can set up an
experiment for yourself. Use a matching network to match 1000 feet of 450
ohm line feeding a 75 ohm TV receiver. You will see layers of reflected waves
as multiple ghosts. Will you deny the existence of reflected waves when you
see them with your own eyes?

> The telephone line echoes aren't a steady state phenomenon but a transient one.

All modulation echoes are transients. If they were not transients, you wouldn't
be able to detect them. The fact that you can detect differences in modulation
means that two+ waves have superposed. Where did the second wave come from?

I don't know what you mean by transient. It is a real echo. The reason you don't hear it much any more is that the telephone company CO uses DSP echo cancellers. Echoes occur at two wire/four wire interfaces, and the far end customer's telephone. In addition to electrical echo, they even worry about acoustic feedback from a telephone receiver back into the microphone. There are all kinds of specs on this. They are really weird about it in Europe.

I'm a little hazy about this. The frequency of time-varying portion of the power wave or waveform is twice the frequency of either the V or I. So when you say the the power is "two complete cycles behind", do you mean two cycles of V or I, or two cycles of the power waveform (which would be half the time interval of two cycles of V or I)? The power waveform also contains a considerable DC component. Is this also reflected? If so, how can it be "in phase" or "out of phase" with anything? If the load is reactive, how do we figure the reflection coefficient for this power wave? Based on the frequency of V and I, or the frequency of the power wave?

Well, that's just false, Peter, as you can prove to yourself by connecting
1000 feet of open-wire transmission line to a 75 ohm TV receiver and matching
the TV signal generator at the other end by trimming the ladder-line to a
exact multiple of half-wavelengths. You will see multiple layering of TV
ghosting, each layer being about 1/4 power compared to the previous one.
Rho will be about 0.77 and the round trip loss on Channel 2 for that 1000
feet of open-wire transmission line will be about 3 dB. I ran that experiment
in graduate school at Texas A&M almost half a century ago except that it
was with a 300 ohm TV receiver so the reflection magnitudes were smaller.
I saw the ghosting caused by reflections with my own eyes.

I have noticed a tendency lately to require reality to match the mental model
rather than vice versa. You latter day gurus have been seduced by steady-state
sine waves. (obviously the work of the Devil :-)

Well, you obviously will need to ensure that no currents flow on the
outside of that particular piece of tubing. How are you going to do that?
Install #77 toroids up and down the entire length?

Peter, AB4BC wrote:
"Direct current or DC transmission is nothing more than AC operated at a frequency of zero Hz.

Yes, but this has significant cosequences. The peak value of d-c is no more than its effective value. A-C of the same effective value (its rms value) has a peak value of 1.414 times its effective value. So, a-c needs more insulation. D-c doesn`t loaf at any point during its constant transmission. The line loss suffers no peaks and valleys.

Reactance does not affect steady-state d-c. And d-c does not usually radiate or induce loss in the earth or other surroundings.

To deny the existance of reflected energy is naive. Too many observers have seen time domain reflection gear work. A pulse encountering a discontinuity is seen to produce a returning reflection right on the scope and the distance displayed on the screen can be translated into a distance from the sender to the reflection point.

Best regards, Richard Harrison, KB5WZI

Tam,

Unfortunately, when a high pass filter is inserted in the test lead it is impossible to prevent it from adding itself to the length of the transmission to the antenna. It seriously upsets the very thing you are trying to measure!

Can only wait until improved versions become available.

2616. Re: Example V-Plane Patterns for HF Verticals? Where?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-17 05:38:13 UTC
From: Larry Higgins <n9dx@attbi.com>
Message-ID: <9XFB9.53974$NH2.3235@sccrnsc01>
Source record: 131205

In my 1984 ARRL Antenna Book, radiation patterns are shown for several heights. 3/8 wave is unfortunately not shown. It also shows feedpoint impedance over perfectly conducting ground. At 3/8 wave, the impedance is 180 ohms radiation resistance, and about 400 ohms inductive reactance. Helically winding the spreader raises this reactance still further, making it more difficult to match. Furthermore, helically wound elements have been shown to be less efficient than straight conductors and good loading components. (For more details, see the archives at topband@contesting.com) With inductive elements such as yours, the series loading component will be a capacitor rather than a loading coil. Two problems then arise: first, with a kw, there will be about 650 volts rms (1kv peak) across the capacitor, and second you will then have a resistive feedpoint consisting of 180 ohms radiation resistance, plus your loss resistance. This does result in higher efficiency, but a matching network will be required if you want to feed it with 50 ohm coax.

The 1994 book (17th edition) doesn't have the same figure. It does have a table (Table 3) in chapter 3 which gives info on radial requirements for ground mounted verticals. For a small number of radials, the radials need not be very long. Figures are for a quarter wave vertical over average soil, with radials. The lengths shown are optimum for the number of radials shown. Excerpting from the table, with 16 radials, 0.1 wavelengths long, the signal is down 3 db below perfect ground. With 24 radials, length is 0.125 wavelengths, down 2 db. With 60 radials, 1/4 wavelengths, 1 db down.

The 1997 book (18th edition) has neither the table nor the radiation patterns.

At 20 meters, 0.1 wavelengths is 2 meters or 6.5 feet; 0.125, 8 feet; and .25, 16 feet. If your space and energy permit, 16 6.5 ft radials isn't much work. Total wire length is 32 meters or about 100 feet. 24 at 0.125 totals 60m (about 200 feet). Still not too bad. It's your choice, but the simplicity of a 1/4 wave vertical fed with 50 ohms and no network is very attractive by comparison. Stretch out the wires on top of the grass and pin them down to keep them out of the lawnmower and you're done. With 20 or so radials, the feedpoint will be very close to 50 ohms resistive.

Roy's explanation is right on the money.

Another way to visualize it is to consider a circular loop. If you feed the bottom or the top, you have horizontal polarization. If you feed either side, it's vertical. And anywhere else, the polarization is slanted.

Roger,

I am not even sure where this thread started, but the whole issue of echoes on a transmission line is much better analyzed in the time domain. You can do a piece meal analysis, and draw a picture of what is happening. Or, look at what is happening with a 'scope. Put a 10 ns pulse into 10 feet, or more, of open circuited 9913, and you can see the pulse come back. The time it took to return tells you how long the coax was. Terminated it in a finite impedance other than Z0, and you can calculate its value. Clearly, if you were doing an experiment, you would repeat the pulse at some frequency, rather than send a single pulse. If the source impedance is not Z0, the echo gets re reflected from the source end, and you get a whole string of pulses going back and forth.

Here is an example of what I mean by piecemeal analysis. Take a 1VDC source, 50 ohm source impedance, and at time T=0 connect it to a 50 ohm transmission line that is shorted at the far end. At T=0, the voltage at the input to the line is 0.5V, because the source does not know that the line is shorted. When the voltage gets to the short, it is 100% reflected, but inverted in polarity. (You can't have voltage across a short). Now, when this reflection gets back to the source, the voltage at the source end of the cable goes to 0.5 - 0.5 =0V. There is no further reflection. So this is the steady state. What happened is that the DC voltage got converted to a pulse, whose width is twice the propagation time of the coax. This is not just academic, they used to actually produce pulses this way (and still may).

Not sure about the Great Pumpkin and the Easter Bunny, but reflections are real, and not a mathematical convenience. (I know you are not the one who said that)

That's not universally true, but depends on the size of the loop and the direction in which you're looking.

Well I understood it until you put it into terms of a circular loop.
Seems to me, if I understand the explanation, that a circular loop
should have equal amounts of vertical+horizontal e-field, resulting
effectively in a 45 degree angled polarized wave for us
vector-challenged types.

Help me out here.

-Bill

OK. Put it this way: Connect the feedline to the loop. Then rotate the loop around a line through its center. The polarization rotates along with it. That's because you are applying the voltage at different angles. Hence the E-field rotates. Or consider a driven circular out in free space somewhere. Vertical and horizontal now have no meaning. There will be current maxima at the feedpoint and at the point opposite the feedpoint. There will be voltage maxima at the points 90 and 270 degrees from the feedpoint. It is the voltage maxima which determine the polarization, so as the loop rotates the polarization also rotates.

And Roy, you're right. It's not universally true. I was assuming a viewpoint in front of the array, and full wave loops.

Hi Evan,

So you mean that usually true mobiles antennas, like "screwdrives"
maybe give better results that "portable antenna", even if I use an
ATU ?

I am very interested in mobile antenna to work in the field, and from
what I have experimented, even with a high SWR some of my friends
reached antipodes (ok their signal is weak but their confirmed their
DX).

Of course as long as I am SWL my problem is different and I can work
with a high SWR if needed. But between a portable and a mobile
antenna, I do not really see big differences... so if you can help me
select one or another model, that could help me too.

Thanks for you explanation.

> lines' distributed capacitance and inductance.

the key words in this argument are 'steady state'.

as the problem is stated, in the 'steady state' you can ignore the forward
and backward parts of the wave and use the simpler formulas.

unfortunately, tv signals, phone signals, ham transmissions, etc rarely if ever are at a 'steady state'. every change in the transmitted signal is a transient and can be tracked by the forward and reflected waves, so even if you are transmitting a plain black or white screen on a tv there is a transient every scan line for the sync and retrace which causes reflections and ghosts. due to the high repetition rate of transients and the relatively large size of the feedlines and antennas the system is never at a 'steady state' condition where you can ignore the reflected waves.

2625. Undecided.

Ok. For graphic purposes then, can I assume the two max voltage points
operating in tandem to essentially create an e-field oriented with this
90-270 line?

No Cecil, in the past in combination designs I have placed
variable capacitors within the boom for weather protection.
On this set up I am starting with just a dipole.
The loop or 'parallel circuit' at the center is now on the inside
the dipole along with the variable capacitor emerging thru
the sides of the dipole via insulated holes
I was thinking that the extremities of the INSIDE of the dipole
would not have any current flow , only where an inserted circuit exists.
Another one of my Rube Goldburg experiments with self imposed challenges.
Thanks for your inputs on this odd setup.

Yes, your previos comment did have an impact because the
radiation of the loop oddly enough has a large impact on
radiation especially down at the longwave portions.
I am investigating more to see if I can make that
omni directional.

Exactly. The assumption being that if two cycles of the sin wave appear to be exactly the same, then they may be considered to be 'equal'. It is an assumption.

Sory that I didn't rrespond earlier Fred,
somehow I missed it.
I would imagine that you have a dipole that meanders
somewhat and probably not at an ideal height such
that the radiation pattern is somewhat omni direction.
The aproach I would take if your interest is purely
80 metres ia to add a parallel circuit about the center point.
Initially I would start around 6 foot from the center moving
a distance of say 10 inches from the dipole and then moving to
the other side of the dipole center before rejoining the dipole.
Any drooping that may occur should not affect anything.
If you leave the feed point in the center the impedance will
change more than you would like (it will become more reactive)
so I would suggest that you feed at each side where the parallel
circuit starts and finishes.
The impedance will be high at this starting point so add
a transformer for starters.
When the pattern starts to take on a bidirectional pattern
you will see the band impedance flatten out some what, that is if the
parallel circuit is around the correct length, at this point I
would suggest that you then move the feed points outwards a bit more
until you have the right transformer ratio set up.
I haven,t worked it all out but it will be a lot easier that adding
parallel line feeds because wire size will not come into play.
If you have any questions regarding this aproach by all means
use the private E mail route. I would caution you however that moving
to a more directional pattern may well not be to your liking.
You should be able to model this form before hand to get closer
to the correct dimensions rather than just trusting my hunches,
it could be a wothwhile time saver.
Good luck with the project
Regards

When I first installed my elevated 4-Square for 40 meters, I cut the radials to the so-called formula length, whatever that was. These are all bonded to the actual vertical element at the base and the element is fed by a gamma match section. Years later, I happened to cut one of them loose and stick a little 3/4 inch diameter three turn loop in there which bridges a common antenna insulator. I stick a grid dip meter coil into the little loop and look for the reasonant frequency of a loop antenna for example. Neat way of determining in practice just what is apparently really going on about what frequency a given loop is at.

Well, as I did this on my sample radial on the elevated 4 Square, surprise! It was WAY low in frequency for the length of the wire as calculated! In fact, it went from about 33-odd feet, I dunno the old value, down to almost 31 feet after I folded back the tip end and shortened it down by folding it back on itself at the insulator support out at the tip! And that at the DX part of the band right down at 7.0 Mhz, which is all I care about anyway for this array.

I was very surprized to find the every single one of the radials I had up there was almost exactly the same scenario. I'm sure that if there was enough time to model it all and so on with a program, the answer would flip out of the computer to match what happened in practice. But the discovery has just re-inforced the experience teach-Mike, that the best thing to do is use the simple tools and techniques to check the stuff as installed.

I suspect that you'll find at least somewhat of the same effect in your work, but heck, maybe not. Just a thought.

2637. Mounting whip antenna on truck for mobile HF

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-17 16:07:00 UTC
From: kb1hfp@arrl.net
Message-ID: <c4a1d362.0211170807.d7a9a9b@posting.google.com>
Source record: 131226

Hi,
I'm currently planning a mobile HF setup for my truck. I have an IC-706MKIIG installed that I've been using with a mag mount for 2m and 70Cm. My plan is to purchase the ICOM AH-4 tuner and use it with a stainless steel CB whip to tune 6m through 40m.
The part that I'm unsure about, which may affect my purchase decision, is how to mount the antenna system. My truck is a 2000 Ford Ranger with a plastic bed-liner and a snap-on leather bed cover. My original plan was to mount the AH-4 inside the wall of the bed and the antenna on the bumper. However, I'm concerned that I won't be able to get a good ground for the tuner, and that the position of the antenna will interfere with opening the tailgate.
I'd be greatly appreciative of any specific advice for mounting the tuner and antenna, or inexpensive alternatives to the CB whip that would work well with the combo of the 706 and AH-4.
Thanks for reading,
Jamie, KB1HFP

hey ron
what you need to look at is the DB rating make sure they both compare to
either DBD or DBI dont try to compare a DBD to a DBI it will give you a
headache
when i was looking into getting a dualband base antenna i looked at
comet and diamond and a few others and i found comet was better had
higher gain for nearly $100 less than the diamond
good luck

hey james
i dont know how you feel about this but go to radio shack and buy a ball mount it would mount on the trucks fender it requires you drill 3 or 4 small holes and one larger hole and then you attach the feedline on the inside of the fender and you could also attach the AH4 there as well as long as it doesnt get wet as for the bedliner you could always cut away a section of it so you could mount the tuner on the inside on the fender wall and be a real short run to the ball mount on the outside of the fender good luck and let me know how it works i am toying with a similar idea but i have a 97 mercury sable that is mostly plastic so i would be interested in knowing how well the AH4 works with the stainless steel whip

That's right. Those two maximum voltage points reach their maximum voltage at the same time, with opposite polarity. Hence there's a large potential difference between them. That's why they determine the polarization of the e-field.

Source record: 131231

Jamie,
By the sound of it, you aren't too enthusiastic about
holes in your truck. If that's so, then you have a couple
of alternatives for mounting an antenna. You can always
put it on the bumper either with some type of bumper mount,
or drill a hole and use a mount that bolts up solid. With
the bumper mount I'd certainly run a ground strap to the
frame of the truck. As you said, with out careful planning
getting the tailgate down might be a problem, though.
There is also such a thing as a 'stake' hole mount. It
fits in one of the 'stake' holes on the bed sides. I would
imagine that will depend on how the bed cover is made, and
how willing you are to modify it.
Mounting the tuner isn't that much of a problem, I would
think. If it isn't mounted directly to the body of the truck
then you will have to use a ground strap (as in mount it to
the bed liner?).
And a word about using a 'whip' on HF. The lower you go
in frequency, the worse it will work. 6 and 10 meters shouldn't
be a problem, but anything lower than that will be. It will
tune, but your signal won't be much to brag about at all. By the
time you get down to 40 meters, you'll be lucky to be heard (the
HF version of a 'rubber ducky'), the whip is just not enough
antenna...
Good luck and have fun
'Doc

Simon,
Counterpoise length isn't critical, but you should
at least be in the 'ball park' with it. I wouldn't
bother about the velocity factor. A few inches either
way won't make a lot of difference.

If buried in the earth, not very precise. If elevated, very precise -- you'll need to adjust the length, then try the rig out in transmit mode and check the swr. Keep adjusting until swr is minimal.

My 706 in the 2001 Ranger I drive uses a Tarheel screwdriver antenna mounted on the rear bumper. One small hole in the bumper and then a bracket higher up coming out of the crack where the tailgate closes. This is out of the way of the gate and doesn't hurt visibility of the taillight like you would think. If you want pics of the installation email me. Not sure where to mount the tuner but realize this setup WILL NOT work near as well as a screwdriver or other resonant antenna.TG

2647. Separation between multiple 2M J-Poles?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-17 17:43:08 UTC
From: Charles Dee Rice <cdrice@pobox.com>
Message-ID: <3DD7D52C.242E686@pobox.com>
Source record: 131235

I've seen several discussions here and through what I've found via search engines concerning mounting multiple Yagi antennas, but I haven't had much luck concening information for mounting multiple J-Poles.

I have moved to a new house and am "reconstrucing" my shack and of course the antenna farm; at this house I have a great place to rather inconspicously mount a couple of 2M J-Poles on my furnance chimney -- but I've never had them in this proximity before and need to decide how far apart to space them.

Would the minimum 1/2 wavelength vertical separation apply to these antennas as well? Would the horizontal distance between masts factor in? Depending upon which corners I mount each antenna, I'd have 23 1/4", 28 1/2" or 36 1/2" horizontal separation.

Has anyone made or seen a J-Pole with multiple radiators constructed from a single mast? Perhaps I could just modify my existing J-Poles and essentially stack them on top of each other, using a single mast?

Does the latest Antenna Book address things like this? My latest copy is several revisions old, and doesn't have anything specifically about multiple J-Poles.

One J-Pole is for use on my packet rig, which stays on all the time, but of course is only TXing for small bursts; the other J-Pole would be for my voice rig. Both rigs run 50W max, but normally around 5W.

Thanks for any advice or online resources anyone can point my to!

- Chuck

My GMC Pickup has three holes for trailer hitch ball mounts.
I just use one of those holes with a threaded rod for my
mobile antenna mount.

Counterpoise length is somewhat akin to off-center feeding
a dipole. Being off-center by a relatively small amount
doesn't much matter.

Hi Jamie,

My buddy has no problem putting the drill to metal; but he also has a very useful mount with one of those large tool chests (it holds the gear too) that ride the rails behind the cab. He chose the gull-wing door style so that the middle third could easily support a whip (military surplus with a hellacious insulator and vivid yellow decal warnings of death on contact).

Hi Danny,

Going to the source is always good. In matters of transmitting
anything, you approach the FCC.

At some point you will have to file something, for your reference:
http://www.fcc.gov/formpage.html

At some point prior, you will want to figure out just which allocation
you qualify for. Consult:
http://www.fcc.gov/oet/spectrum/table/fcctable.pdf

Hi All,

I was struck by the nature of appealing to the senses to make a technical point. Seeing is believing and yet sight is fraught with the most potent of problems: interpretation.

Blind at the lab bench, yes, with a standard configuration of instruments associated with Watt levels, the reflections being discussed are invisible to the process. Or more to the matter, imperceptible to the investigator.

Dazed in the living room, yes, as Bill so compelling argued, we find that the instrumentation available is exquisitely tuned to this particular spectrum of noise. This instrumentation would go to the rails if driven with Watt level signals.

Hi Peter,

You lost it at the gate. You cannot explain Cecil's easily understood
and experienced example with a misapplication of group delay.
Dispersion and group delay result in an easily recognized and visible
effect called "smear" that is distinctly different from the visible
effect described by Cecil.

Then again. On reflection of the many occasions when you posted the
group pool-side, drink in hand; then I suspect many "ghosts" you see
on the pool-side TV may have some bleariness. This constitutes
Bacardi group delay (more a problem of low-Q synapses than
Transmission Lines). ;-)

Lots of flat land. Not inclined to build a tower. Considering a horizontal wire along top of fenceposts, held apart from wood by electric fence type insulators. Would this type of antenna (end-fed or dipole) be at all useful? I realize the height is less than optimal but I am not willing to add any man-made structures to the beautiful landscape apart from what is already here.

The situation you describe would seem ideal for constructing a
beverage antenna. Unfortunately, beverages are normally used
only for receiving. Plug "beverage antenna" into google and
see what you think.

Heh, heh... There ya'll go again!

But... but... guys you can't have it both ways! Either CW has reflections
or it does not, now which is it?

Whenever you are using your so-called SWR meters to adjust your
antennas/tuners etc...

Which meters apparently ya'll claim are resolving the forward and reflected
components
aren't you measuring with a continuous wave [CW] signal?

If, as ya'll assert that the steady state is not a valid method of
evaluating reflection mechanics.

How then does the SWR meter work? Will it work at DC? Can it be made to
work at DC?

What???

I made an SWR meter once using resistors, a diode, and a capacitor. Some people might have called it a Wheatstone bridge. I'm sure it would have worked at DC, and the capacitor would have been less busy.

> What???

No -- where and when? (Answer: At W8LT, The Ohio State University amateur radio club, in the late 1950s.)

The thing was intended to be used to check the calibration of a more conventional "SWR meter" that had been constructed by snaking a short piece of hookup wire underneath the braid of a section of coaxial cable.

Oh, I thought he was talking about steady state, with no modulation.
What kind of modulation are we assuming? If it's TV, you could assume a
"Cycle of symbols" to be a line, field, or frame. Do you mean you'd have
a delay of two full lines, fields, or frames?

Like so many other things, it depends. Usually, it's not critical at all. The only time I know of when it's important is when you're using an elevated radial system fairly close to the ground. And in that case, it's ok to have them too short, but efficiency suffers if they get too long. You can determine what a resonant length is by erecting or modeling a dipole at the same height as your radials, and adjusting it for resonance. The length of a resonant radial will be half this length. If it's close to the ground, this length will be considerably shorter than a resonant length in free space. If you're using an elevated radial system, I recommend that you don't make the radials longer than the resonant length. If you're so inclined, you can see by modeling what the impact on efficiency is by making the radials too long.

Hi Roy,

Yeah, pretty much on a line basis for nearby reflections when talking
about TV. Less would suggest a fraction of a line as an arbitrary
symbol element (as in your less than 62ï¿½S reflection example). For
digital traffic, slightly more than half a bit would seem to be the
metric of the day.

20 odd years ago, computer board builders began to suffer mismatched
connections in the backplane or peripherals and started to pay
attention to reducing SWR. This was even before the IBM PC 4.77 MHz
standard. Some old hands may remember the 9 resistor SIP that
terminated the last hard drive's connection.

Source record: 131257

A simple question--but I can't seem to find a definitive
answer anywhere . . . can anyone tell me the _minimum_ effective angle
between the two legs of an inverted "v" antenna?

My installation would require the two legs to anchor
approximately 12' apart (at 13' above ground) in order to fit my
location. Using, for example, a 30-40' pole at the peak of the "v",
would the antenna provide a satisfactory installation (the point of
the "v" would be due West with the legs due East)?

Responses by email or here would be greatly appreciated--as
would any feedback on the Yaesu YA-30 tuned dipole antenna, which I'm
hoping to use for the installation.

Thanks in advance,

> 28 1/2" or 36 1/2" horizontal separation.

Depends if they are end fire or broadside arrays. Usually, about 1/8
wave spacing gives the most gain from an end fire array. For a
broadside array, anything from a 1/4 to a 5/8 wave will work with
different patterns for each spacing. Generally, 5/8 spacing gives the
most gain with a broadside array.
You can easily model this and see the patterns with each shift in
phase for any given spacing. When modeling, you change the phasing by
changing the source.
IE: say two 1/2 waves are both fed in phase. "0" degrees of phasing
for each element. If you want to shift 90 degrees with one element,
just change the source to "90" for one of the elements. You can see
that reversing the numbers shifts the pattern in the opposite
direction. Any of those spacings you state can work, but will differ
in the patterns available. I would model them to see exactly what you
will get. Saves a lot of time and testing on the air...You'll know
about what to expect before you even put it up.
>
> Has anyone made or seen a J-Pole with multiple radiators constructed from
> a single mast? Perhaps I could just modify my existing J-Poles and
> essentially stack them on top of each other, using a single mast?

Sure, you are describing a "collinear". You can stack 1/2 waves or 5/8
waves. An isopole or ringo ranger are stacked dual 5/8's antennas. The
method butternut uses for their "trombone" type dual 5/8's verticals
are the closest thing I can think of to a "collinear J-pole". Some
make dual 1/2's or 5/8's out of copper. You have to add a phasing stub
between the elements..
>
> Does the latest Antenna Book address things like this? My latest copy

Dunno...I don't have the latest issue. My newest one is like 94 or
something like that..
>

>
> Thanks for any advice or online resources anyone can point my to!

Want real performance? Get a small 3 or 4 el yagi. It'll blow the
verticals out of the water usually, and needs only one support. It
does require a rotor though if you want to turn it or go out an
manually turn the mast. A vertical should be fine for the packet
though.. MK

Hi Peter, good to see someone is getting himself up to date!

In the current drive for 'political correctness' - re-title SWR meters as SCSWR meters.

Or even better: TLI's = Transmitter Loading Indicators.

- a fully apt and far less confusing and disrupting description of the mis-named instrument for Guru's, Hams and CB-ers alike.

Comrades, let's all to the barricades - Vive La Revolution et L'Amateur Radio !

Hurry the Old Wives in the tumbrills, by the shortest route, to Madame Guillotine. She awaits, in anticipation, suspended !

Incidentally, what is the optimum height, weight and cutting angle? Didn't the Scots take out the first patent before the Bastille was stormed in 1792? But it was the brilliant French aristocratic mathematicians of the time, of course, who perfected the machine and indeed a few were amongst those who perished under her blade, spilling their blood along parisien gutters to the sewers and then to the Seine.

But during the same period of time, in the crowded English slum towns, far, far more people died of the cholera, typhoid, the plague, starvation, men, boys and mothers down the coal pits, and amidst the furnaces, engines in the primitive iron works and cotton mills. They were the innocent victims of another sort of revolution - the Industrial Age had already begun with even greater vengeance!

In these days of enlightenent we have now advanced to 24-hour porn on the telly to entertain our overweight, ill-educated, ignorant, gun-toting grand children. Where are the Weapons Inspectors?

Oh yes, I almost forgot - when is the asteroid due?

Have a good day and good DX folks. Hic!

It's not a valid method because the reflection mechanics are hidden
in the steady-state smoke and mirrors that you guys use with your
magic wave disappearing act. :-)

With a DDS source, you can program a different phase per cycle, i.e.
if you are careful, you can identify each individual cycle by its phase
modulation. Track the phase interference to see what happens to the
reflections.

The reason you can't find an answer is that there isn't one.

As you decrease the angle, the radiation resistance decreases and the bandwidth narrows. It's up to you to decide when the resistance or bandwidth is too low for you. People who don't want to bother with making these decisions often limit the angle to no less than 90 degrees, since this yields a radiation resistance and bandwidth most find acceptable.

You can easily find the resistance and bandwidth for any angle with the free EZNEC demo program from http://eznec.com.

> Best regards, Richard Harriaon, KB5WZI

This is valid only in the far field, where the E and H fields are in time phase and have the ratio of 377 ohms. In the near field, you have to know both the E and H fields, magnitude and phase, in order to calculate the power density, since the ratio of E to H isn't 377 ohms, and can be complex. But I believe that most authorities imposing radiation requirements (such as the FCC) accept the conversion Richard gives for compliance purposes, even if it isn't particularly accurate.

Charles Dee Rice wrote:
"Does the latest Antenna Book address things like this?"

Maybe not exactly what Charles wants, but edition 19 of the ARRL Antenna Book has a collinear J-pole called a "Super-J antenna" on page 16-25. The two half-wave radiators are separated by a perpendicular short-circuit 1/4-wave stub to perform the necessary phase inversion. The usual base stub is used to match the feedline.

If vertical antennas are to be decoupled and mounted on the same axis, two wavelengths at the lowest frequency is a reasonable minimum, but less separation also works.

Best regards, Richard Harrison, KB5WZI

Use No-Alox, Oxgard or similar (check the electrical department of your
local hardware store or an electrical supply house). These are a
grease with suspended conductive particles (not paint).

Hi Dale
The eaisiest way to do it is to get your hands on some "entrance fittings" for your size cable. Often called stingers by CATV people. These are the fittings that go into the amplifiers and splitters. Common items at swapmeets and CATV trucks $7.00 brand new.

They have a 3/4 24 thread on the end that goes into the housing. Just solder a center pin on it and screw it into the back end of an N connector. Very trick & weather tight. Trim cable length to give 1:1 VSWR with 50 ohm on far end.

Gordon, exactly what are you making so that the parameters of use can
be gauged?
Ive seen mention of both plate and rod and now you mentioned
machining.
As an engineer many facts would have to be known before a reasonable
material can be suggested. For instance I once needed a specialty part
and eventually finished up creating a mix of epoxy and brass filings
to mold a specific part which is still in use today. Yes it proved to
be a good material but for you I have no idea.Same with epoxy glass
boards which when painted work just great
but for your use again I have no idea.

I was licensed in 1970, as WN8EIY, later WB8EIY and W3JXP is a vanity call. I became tired of people turning their antenna the wrong way when they heard the 8 land call after I moved to Pennsylvania. Also many of the southern boys had a real problem with the "I" in the call. As much as I hated to give up a call I've had for so long, it was time. Its my email prefix here at Penn State. I am a seasoned ham as I've now been licensed for more than 30 years. I was thinking it about a bit ago, and by my recollection, the longest length of time I've gone with out transmitting on a ham band is 30 days, when I was working in Europe and couldn't get a license in time to take it with me. I started work as an electronics engineer in the Physics dept. at Michigan State University in 1970. I then moved to Penn State University as part of a High Energy Physics research group in about 1982. Here I run the electronics shop and design and build research and teaching equipment. You are some what correct about how grad students are used. But the idea is that when they get their PHD they can then pass it on, the dirt jobs that is, to others. That is the time honored system that has been used in colleges from the day colleges started.

All Hail Bush!

Or so starts the report from Durham, N.H. where Holly Ramer of the Associated Press reports of the efforts of one Brian McWilliams to snoop on email sent TO Saddam.

Seems he stumbled across an iraqi site that offered a means to submit and read email. He simply entered press@uruklink.net (Saddam's account) and used "press" (for president) as the password - BINGO! He then had access to a treasure trove of mail from folks all over the world. McWilliams wrote about this in several publications since last summer, and notified the government. The government (our tax dollars at work) has yet to respond. To quote our great leader, this is going to take time - if we leave it to the politicians that is.

Apart from the obvious lack of interest from those whose job is presumably security (seems to infect both sides); McWilliams also revealed how some American firms were clamoring to do business with the great Satan. And here we get to something that borders on interest to this group.

"... despite U.S. prohibitions against such transactions,
McWilliams said ... company e-mailed Saddam to request a meeting,
suggesting they could discuss 'technology improvements and
exporting of rich technology abroad.'
He said the company ... claimed to have developed wireless
technology capable of 'igniting large sections of the
atmosphere.'"

McWilliams added it all revolved around communications antennas. That company, of course, has not been approached by the FBI in this era's new concern for security (it will take time). And perhaps for good reason considering the claim. Perhaps those agencies follow the debates here and take stock in our efforts to debunk nut-fringe activity. However, it would seem prudent if the SEC looked into this bunko operation - but then the administration's track record of ferreting out the business bozos and their shills is no better than finding Osama Waldo (I'm beginning to wonder if he dresses in a striped shirt and wears glasses and a stocking cap).

The bottom line appears to be that those of the intellectual calibre and emotional fitness of catering to Saddam/Enron/Anderson seem prone to propagating get-rich-quick schemes that unfold around fantasies draped in the psuedo-science of eh/cfa/fractals. Now doubt the coming term will open up the floodgates of the tax coffers to dole out juicy contracts to develop antennas capable of "igniting large sections of

the atmosphere" as a means to cut the antenna-gap. Yes, this could take a very long time (that hand riffling through your wallet is the fist of security).

Thanks for the advice; maybe I'm misunderstanding, but I'm not sure
we're
on the same page here. :)

We are not. My mistake..I thought you were trying to phase the antennas.

I want the antennas to act completely
independant of each other (minimal interaction) -- since one is for a
packet rig and the other general-whenever-I-feel-like-it voice
operation.
I don't want one rig desensing the other every time it transmits, and I
don't really want to impact the radiation pattern of either antenna.

Got you. I'm not sure what would be required with that. I've never had
to try it, and never have done any work with repeaters, etc in order to
know the best methods of seperating. Desensing probably would be a
problem.

> Sure, you are describing a "collinear". You can stack 1/2 waves or 5/8

Read a little about those, too -- but couldn't find any information on
simultaneously transmitting on both elements, or what effect
transmitting
on one has on the other. Maybe I just didn't read enough about them
yet.

Those won't work for what you want to do. They are single antennas.
Maybe some others will have better ideas for you. I think Richard stated
two waves apart are ok, but I'm not sure if that would be enough to
avoid desensing problems or not. Thats pretty close together. MK

Tarmo I have a 100' long wire about 10 feet off the ground connected to tuner and it works well. My long wire is just a piece of 14 gage wire looped through the limbs of the trees at various angles and connected to the MFJ Tuner. It's great for monitoring everything from the AM broadcast band to 30 MHz. I have used it on transmit through the tuner on 40, 20, 15 and 10 meters. It's nothing fancy but it works and it's not expensive by any means.

Yes, they're the same. The term "counterpoise" is used by amateurs to mean a part of the antenna that doesn't radiate significantly. Although buried radial wires fit this description, the term "counterpoise" is usually applied to an elevated, rather than buried, system of wires. So most amateurs wouldn't describe a system of buried radials as a "counterpoise" even though that's what it amounts to.

If not ground mounted, a taller structure is required and the counterpoise is up in the air. If it's operated without a counterpoise, efficiency suffers. Don't believe any manufacturer who claims otherwise, unless the whole system is at least a half wave above ground. Even then, there will be plenty of rf current flowing on the outer surface of the feedline, and that current changes the pattern and heats the worms.

Why not ground mounted? Ground mounted verticals are structurally simpler, and with even a modest set of radials they are fairly efficient. For example, as few as 16 radials, each 0.1 wavelengths long, is down only 3 db from perfectly conducting ground. That's many many db above the wire above the fence. On 20 meters, 0.1 wavelengths is 6.5 feet. So the whole radial system requires only 100 feet of wire, which can be installed in less than an hour. Going to 24 radials 0.125 wl picks up another db, and is still only 200 feet of wire.

A 20m 1/4-wave vertical is only 16 feet tall and can be easily fabricated. A triband vertical is about the same height. Since aesthetics are important, such an antenna could be rigged with an extended base and plugged into a hole in the ground when in use, and unplugged for storage when not in use.

Message-ID: <4c442fa0.0211181147.57b89710@posting.google.com>
Source record: 131145

Hello,

I am in the home stretch of putting the tower up. The appropriate paperwork has been filed and the hearing is this Thursday for my permit. The plan is to put up a 17.5' Glen Martin roof tower on my garage. The garage is about 14.9'. I will be putting more supports in the rafters than the instructions say. I am thinking of getting the next higher tower, the 26' one. That would put the antenna up at 40.9' instead of the 32.4'. I am more concerned about the safety of the higher tower than the cost. (I have the money for either). Also, how much mast can I put out the top of the tower? There will be about 2' in the tower. I will have a 5 band Hexbeam up which is 5sq ft of wind load.

Thanks!

Jason Hissong

My own experience with 5-band verticals without radials is that they are excellent on 10, very good on 15, pretty good on 20, fair on 40, and very poor on 80. Add radials and performance improves on all bands, with the most improvement on the low bands.

Since you are 75, I can see why you don't want to dig up your yard for radials. That's not necessary anyway. What I did for mine (and what many others have done) is just lay the wires on the grass and pin them down with six inch pieces of #12 or bigger, bent in half to look like large bobby pins. The grass will soon overgrow them and your lawnmower won't grab them. Or, if you live where you don't have to mow the grass year-round, just lay them on the ground in the fall and roll them up in the spring.

"Putting down radials" usually means putting them on top of the ground, either permanently or temporarily. If permanent, they are held down with pieces of bent wire to hold them down until the grass grows over them. That's what was done here at N9DX and by many, many others. If temporary, just lay them on the ground and when you're finished with them, roll them back up. That's what we do for field day.

"Burying radials" means just that. You can use a shovel, or a shallow plow, or special equipment made for the purpose. Go just deep enough to protect them. Broadcast stations bury theirs. So do people with a lot of energy and time.

Electrically, there's little difference. Burying them just protects the wire better.

BTW, make them from almost any copper wire. Don't use aluminum; the acid in the soil will quickly destroy them.

I went through a lot of frustration when I first got licensed for HF, trying
to get dipoles at 15 -20 feet to work for transmitting. Finally, in
desperation, I gave a guy in NM a call on 15 meter SSB, using a 6 meter beam
in the attic, about 10 feet off the ground. SWR was 8:1. He came back to me!
But that was during a contest. First antenna I had that I could work DX with
was a JR tribander at 30 feet. I don't think he is going to be happy with
the antenna at 6 feet, but it all depends on what his expectations are.

Larry, N9DX wrote:
"BTW, make them from almost any copper wire. Don`t use aluminum; the acid in the soil will quickly destroy them."

That`s correct. An acid, base or salt in the soil forms a battery electrolyte when damp. Dis-similar metals become electrodes. The less noble metal is disolved in the solution to migrate in the current flow toward the more noble metal, as the zinc can disolves in a flashlight cell as its current flows toward the carbon electrode in the center of the cell. Zinc sacrificial anodes are often attached to iron and steel to protect the iron and steel from rusting away.

Here is about half the list of metals starting with the most anodic, or most likely to be sacrificed. The farther apart on the list, the higher the voltage of the electrolytic cell (battery) the two metals will make when immersed in an electrolytic solution, and the faster the anodic material is likely to be consumed.

1. Magnesium
2. Zinc
3. Aluminum
4. Cadmium
5. Steel
6. Casrt Iron 7.
Stainless Steel
8. Lead-Tin Solder
9. Lead
10. Tin
11. Nickel
12. Iconel
13. Brass
14. Copper

The list goes on, graphite, a form of carbon is no. 25. It is follower by gold and platinum which are not often found in batteries due to their cost no doubt.

Electrolytic protection whether by impressed current from a rectifier or from a zinc anode bolted to a piece of steel is called "cathodic protection". The steel is the cathode.

A battery of zinc and copper in a solution has a negative polarity zinc anode and a positive polarity copper cathode. This is opposite from a vacuum tube`s positive anode and negative cathode. But, such batteries were in use long before the vacuum tube was invented.

Best regards, Richard Harrison, KB5WZI

Larry,
&#65533; hear you, but ground mounted vertical. or the horizontal at 6 feet for that matter, scare the daylights out of me when close to people. I would prefer to keep most of the RF out of the house. Also, he may not want the vertical with the radials, because he would have to put it where he has to look at it. If I did not have any trees, and did not want to put up a tower (I have a Wilson 45' tubular), I would stick a 12-15 foot piece of pipe in the ground (and ground rod), and support it to the back of the garage with TV hardware. Now mount a no-radial vertical on the end of the pipe. As for asthetics, I think some of them look almost pretty (?!). Not optimum, but people get out with mobile antennas.

Radials are normally balanced so if they are high enough in the air, their
fields cancel in the far field. A counterpoise can be a single wire. If you
have two counterpoises radiating in opposite directions, they are normally
called "radials". A single wire is normally called a "counterpoise".

Relevant item in the November issue of Monitoring Times. Science teams
in the Arctic use SSB rigs on 1.6 - 10 MHz with dipoles strung between
two skis stuck in the ice

I'm currently playing with a random wire about 100 feet long and 12 to
20 feet above ground with a remote automatic antenna tuner at one end.
Results seem to be quite acceptable throughout the HF range.

I don't think the wire along the fenceposts is an original idea - I seem
to have read of this being used with some success at various times over
the years. Try it, what do you have to loose?

Yes, you are going onto the CB band with equipment that is not type-approved for that service.

Ham radio is unique among services in that it is legal to operate with transmitters that are user-built and/or user-modified. AFAIK, no other radio service can do this (legally).

Due to having been off the air for a number of years I am not up-to-date
with the opinion/capability of the "no radial" verticals.

I am considering a gap or an antenna described in the 1977 arrl antenna book.
This antenna is elevated, 30' radiator, a single 30' 'radial' or counterpoise
and fedd with twin lead.

Any opinion on the relative performance capabilities of the two?

thanks,

From an RF standpoint, ice is very different stuff than water. Even pure water is very lossy at RF due to the molecules attempting to align with the field over each cycle. In ice, the molecules are fixed in place, so ice ends up being quite a low loss dielectric.

In my early days of ham radio, I worked plenty of stations on 20 meters using an end fed half wave of thin wire going more or less horizontally out my second floor bedroom window to a five foot or so high clothesline pole in the back yard. (The ground sloped.) With moderate power you'll be able to work lots of stations with your antenna up only six feet, especially on the higher frequency bands. You'll get frusrated if you try working much DX, though, and please do take care that no one will be able to contact the antenna when you're transmitting -- especially the high voltage points.

Roy, W7EL wrote:
"This is valid only in the far field---."

As Sagan might have said, the far field extends for billions and billions of wavelengths; the induction fields are only of consequence for a few wavelengths.

We even have problems with measurements in the near field because the electric and magnetic fields decline at different rates within the near field, that is, at close distances to the radiator.

The far field has been used to communicate with space probes at millions of miles for exploration of our solar system. The near field is trivial for most purposes other than its involvement in establishing the far field.

Any antenna is better then no antenna. Why would you not want to put up a large antenna if there is land galore? At 13 years old and only two weeks to study, haveing my ham licence was a very big deal to me. I feel the same way 9 1/2 years later. Everyone to there own...
BTW, THERE IS NO PERFECT ANTENNA. Put up whatever you can and use it. If you use the random wire type, invest in an RF counterpoise like the TenTec 1251.

Mark Keith, NM5K wrote:
"---I`m not sure if that (2 wavelengths) would be enough to avoid desensing problems or not."

I agree. It depends on frequency separation and how effective the filters which separate the frequencies. A repeater operates full-duplex, so it always needs to avoid desensing problems. Some choose to use the same antenna for simultaneous reception and transmission. Often this is successful. The price paid is a string of cavities in most cases. Transmitted energy can be mostly kept out of the receiver with careful adjustment. Ham installations of this type that I`ve seen had inexperienced tinkers upset the precise adjustments requiring experts to remake the proper adjustments.

For hams, separate antennas with plenty of vertical separation between receive and transmit antennas on the same axis may be the best arrangement. Commercial repeaters do quite well with a common antenna for simultaneous reception and transmission. But, they are not subject to tinkering by unauthorized operators.

Best regards, Richard Harrison, KB5WZI

Hi Mark,

This Richard hasn't been following closely until the mention of repeaters and desensing. As such the proximity of antennas of the same band are specified by system loss between the transmitter (not the antenna) and the receiver (not the antenna).

For repeaters you need something like 50dB loss (ï¿½30dB, I'm winging it). To achieve that loss you can put a notch filter at the receiver that snubs the transmit output (plus usual gains and minus usual losses). Or you can move the antennas apart.

I am part of a repeater system that has a 10M allocation. The distance method is how we solve the desense. I am 600 wavelengths from my buddy's receive antenna (we link on 220MHz). This is quite common for this band because of the frequency split requiring razor sharp cavity filters (for more reasons than desense) that present a test of the wallet or your skills in swapping. These suckers are at least as big as a standard hot water tank.

standard web warning: your mileage may vary.

Notch filters at each receiver for each Transmit frequency may get quite excessive too if you demand simultaneous multi-channel operation.

I seem to recall that it is not uncommon to be forced into the near field when making compliance measurements. The reasons might include regulation, physics, budget, instrument sensitivity, or chamber size.

Dave Holford wrote:
"Science teams in the Artic use SSB rigs on 1.6-10 MHz with dipoles strung between two skis stuck in the ice."

We used SSB for base and mobile stations during oil exploration and production on Tierra del Fuego. High antennas and VHF FM work a lot better. We switched rather than battle the HF. On the other hand, HF worked quite well in the Amazon jungle for us. HF also worked very well for us between Tierra del Fuego and Buenos Aires but we erected a rhombic on Tierra del Fuego aimed at Buenos Aires.

"Electrical Communication Systems Engineering" written for the War Department in WW-2 by leading scientists at Harvard and MIT does not casually dismiss low antennas because in reality often a low antenna may be the only recourse. These experts said to get a wire up as high as possible, if that didn`t give away your position, but that lower might well work, and that even a wire laid on the ground might do the job. They said you would need a versatile tuner. Even below 800 KHz, a low wire might suffice.

ECSE says:
"The flat-top is a grounded vertical antenna (Marconi) with a horizontal top to increase the capacitance of the antenna, Flat-top antennas supplied by Army Communications Service consist of one or more horizontal parallel conductors supported by two masts with a vertical down-lead at the center or at one end. Thus the antenna takes the form of a T or inverted L. Most of the useful radiation occurs in the vertical portion, or down-lead. The horizontal section acts to increase the effective height of the antenna---. ---always worked against ground---."

J. Harvey wrote:
"I seem to recall that it is not uncommon to be forced into the near field when making compliance measurements."

I`ve done well using a multimeter switched to an a-c scale as a signal strength indicator perched on the hood (bonnet) of a Land Rover (actually many Land Rovers) while I used it to pick the best loading coil tap for the whip antenna. The carrier was reinserted to produce an indication on my multimeter. No other determination improved over the multimeter on the hood method and it was quick and simple.

For pattern or signal strength determinations, I`ve always measured the far field signal whether I was receiving or transmitting. FCC requires broadcasters measure far field signals. However, I don`t doubt a correlation could be established under carefully crafted conditions so that meaningful measurements could be made using the near fields. The sampling loops on the towers are certainly in the near field and they work like gangbusters. It probably isn`t worth the risks of error and trouble to establish and maintain the necessary conditions in most cases.

Best regards, Richard Harrison, KB5WZI

The amount of isolation you get from antenna spacing on the two meter band will be about the
following amounts: The spacing is measured from center to center of the antennas.

With vertical antenna spacing (one antenna mounted above the other) 10 feet will give around
35 db of isolation. 5 feet gives 22 db. 20 feet gives 48 db.

With horizontal spacing of 10 feet you will get only about 21 db of isolation. 20 feet gives 26
db. 40 feet gives 33 db.

When duplexing it depends on how much frequency separation you have as to how much total
isolation you need. As an example with a good commercial two way radio in the VHF band:
At 1 mhz spacing the receiver requires 60 db of isolation and the transmitter requires 75 db.

A single 6" diameter 1/4 wave notch cavity will provide about 30 to 35 db of isolation. So it
would take two notch cavities in the receiver line and two in the transmitter line to get the
required isolation to duplex on one antenna.

The notch in the receiver line is tuned to reject the transmitter carrier frequency. The notch in the
transmitter line is tuned to the receiver frequency. It rejects the broad band noise coming out of
the transmitter.

If you were to use separate antennas then whatever antenna isolation you have could be
subtracted from the amount of cavity isolation needed.

Only problem is, the notch cavities are very sharp and you can not move frequency but only a
few kc before rejection starts to disappear.

Pass cavities can be used also. They will provide a little wider window to operate in but it takes
more of them to get the same amount of rejection at the 1 MHZ spacing as the skirts on the
pass cavities are not very steep.

To answer your question, you can mount the two antennas on the chimney but one radio will
desense the other any time they are keyed up. That is unless you go to the trouble of adding
cavities.

In Richard's case with the 10 meter repeater, if it was on one antenna he would need four 10"
cavities that are each about 8 feet tall and each weigh around 30 pounds each.

Without radials, many verticals work. With radials, they work much better.
One radial is better than none. Many are better than one.

The myth that radials are not necessary for verticals is mainly propagated
by people who want to sell vertical antennas, but don't want to scare you
off by saying you need a lot of radials. And those who say their verticals
work just fine without radials are telling the truth, but they are often
very pleasantly surprised when they install radials and find out how much
the performance improves.

There's no free lunch; just lunches with less food, cheaper.

No disagreement. But, consider a dipole. In free space, horizontal or vertical may have no meaning as horizontal may mean parallel with the earth (actually tangent), and vertical may mean perpendicular to the earth. A distant earth may not significantly affect dipole operation whether horizontal or vertical.

Placing a dipole near the earth affects the dipole.

A vertical dipole won`t need radials to complete its circuit as an antenna. It`s centerfed

But without radials some of its energy may couple into lossy earth and be mostly lost. Radials may be able to decouple the antenna and hide the earth from the energy which would be in part lost in the earth. Over sea water this earth coupling might be an asset in focusing energy at low elevation angles instead of wasting it as poor soil might. Over poor soil, radials could help.

"Dual Tone Multi Frequency", often referred to as "touch-tone". Think
"phone-dialing tones"... each number or letter on the touchpad sends
two audible sine-wave frequencies.

>"A Radio Shack 33-memory Tone Dialer will be used for DTMF uplink control. "

An inexpensive, easily-available, portable device which you can use to
generate DTMF tones for individual digits... or "memorize" a sequence
of numbers, and then "speed-dial" that number. Has a speaker output,
I imagine, which you can hold up by the mouthpiece of a telephone (or
the microphone of an HT or other radio).

Many ham-radio HTs can send DTMF from their keypads, but many cannot
(and those that can, don't have pre-programmable DTMF memories).

>Normally we need cable,or DSL or Dialup to communication with another
>machine. what is DTMF? Are they sending / receiving signal from something

They're controlling something, by transmitting sequences to it over an
audio channel (presumably an amateur radio transmission).

2733. Re: vertical antenna question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-19 07:31:48 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <utjq716scj9873@corp.supernews.com>
Source record: 131071

The claim that there's significant loss in the ground near a vertical dipole keeps appearing. Yet modeling shows very little energy lost to the ground from a vertical dipole. The way to determine this with EZNEC (including the demo version) is to first model the antenna with MININEC ground. With this kind of ground, the near field loss is zero, since the ground is assumed to be perfect during the calculation of impedances and currents. Note either the maximum field strength or the Average Gain. Then repeat with High Accuracy ground. The difference in field strength or Average Gain represents the near field loss. In modeling tests I've run, it's been less than 1 dB.

Do you or anyone else have references that give this supposed loss quantitatively?

I am looking for your vote as to which brand/model of 2 meter antenna's you think is the best. What I am looking at is that it must be Magnet Mount and be of the maximum claimed gain possible, as well as your personal opinion of the specific antenna. I need to replace the antenna I have been using for the past 2 years, that has taken serious abuse and needs replacement.

Thanks,

Depends how high you mount them, but overall, I'd prefer the antenna
in the book. It sounds like nothing but a dipole with one leg standing
up. With the ladder line it would be fairly efficient on most bands
from it's resonant 1/4 wave frequency on up. It will perform
differently on each band, due to being a different length IE:
1/4,1/3,1/2,5/8,3/4 wl per leg, but for the price vs the GAP, I'd go
that route. It would be cheap to build. A GAP vertical is not cheap to
buy. I'd almost bet money it would beat the gap on 40m if it were
elevated at nearly any height. It's nearly a full size antenna on 40m.
1/4 wave up at the apex would be nice. Higher, better yet. The only
problem with that scheme are potential common mode problems, but I
don't really think it would be too much of a problem. The antenna is
fairly balanced. You would need a tuner of course, or use Cecils
measured line method. You could easily model it to see how it would
act on each band you want to work. It would work well on 17m I bet...

From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <ard5mo$2c7$1@helle.btinternet.com>
Source record: 131075

A vertical with no radials is just a very short horizontal dipole, fed somewhere along its length, resonated with loading coils to behave as a half-wave antenna and then rotated through 90 degrees to become vertical.

It will always be less efficient than when in its original horizontal orientation because, on average, for the same height it is nearer the ground. That's the price to pay for its compactness in the horizontal plane. But they do work after a fashion.
Compare overall heights from one manufacturer with another as a measure of performance. The higher the better. Just as the longer the better for a short horizontal loaded dipole.

By all means try a no-radial commercial vertical. But you may find at your QTH you get somewhat better performance with a simple, home-brew bottom-loaded vertical plus a very modest ground system. Specially on the 80 and 40 metre bands.

The best place for a no-radial vertical is on the higher frequency bands on the top of a tower block where there is no chance of finding a good ground system or perhaps any room for horizontal radials or counterpoises.

When forced into compact HF antenna situations don't skimp on the tumer and be prepared to work on fewer bands.

Reg, G4FGQ

2739. Free antenna modelling package

As I got some very positive reaktions on my new 5.0 version for the 4nec2 antenna modelling software I would like to inform others about the existance of this freeware.

Some of the features:

- Especially suited for ham usage because of zero costs.
- Real-Time 3D-graphics viewer using hardware acceleration.
- Use nec-2 models containing up to 11000 segments.
- Incorperates AO based optimizer.
- Display far-field in polar- or 3D-view and compare patterns.
- Display near E- or H-field in chart- or 2D/3D-view.
- Interface with VOACAP/ICEPAC propagation prediction freeware.
- and more...

See www.qsl.net/wb6tpu/swindex.html and look for 4nec2 or view the example images.

I am relatively new to this group, so if it's someones opinion that these kind of messages should not be posted in this group, please let me know.

Arie.

Hey folks,

Thanks for the many responses!

The antenna handbook says of the antenna I mentioned
that "Although the radiating part is only about a
quarter wavelength at 3.5 MHZ the efficiency, too,
would be higher than it would be with a grounded
system." (It referred to 7 MHZ earlier.)

If I understand correctly, the issue with the grounding
system of a vertical is efficiency.

The only guidelines provided for height were that
it would work better if it was on the roof of a
house. I intend to put it on a 10 foot mast.

Based on the responses I think this antenna deserves a
try before I spend the $100's of dollars for a commercial
ant of the same ilk.

Sure wish I had the means for a "side-by-side" comparison
of this, a commercial half wave vertical, and monopoles
installed in various ways. Now that would make for good
reading I would think.

Roy Lewallen, W7EL wrote:
"The claim that there`s significant loss in the ground near a vertical dipole keeps reappearing. Yet modeling shows very little energy lost to ground from a vertical dipole."

If the ground were a total loss, it would be as if it did not exist and energy contacting the earth would not be reflected to help or hurt transmission in a desired direction, perhaps.

Modeling is a wonderful tool but the product depends not only on the tool but on how the tool is used.

Roy also wrote:
"---Average Gain represents the near field loss. In modeling tests I`ve run, it`s been less than 1 dB."

Edition 19 of the ARRL Antenna Book is available to many readers. On page 3-13 is found: Vertically Polarized Antennas. It says:
"In the case of a vertical 1/2-wave dipole or a ground-plane antenna, the horizontal directional pattern is simply a circle at any elevation angle (although the actual field strength will vary, at different elevation angles, with the height above ground). Hence, one vertical pattern is sufficient to give complete information (for a given antenna height) about the antenna in any direction with respect to the wire. A series of such patterns is given in Fig 16. ---In short, far-field losses for vertically polarized antennas are highly dependent on conductivity and dielectric constant of the earth around the antenna, extending far beyond the ends of the radials used to complete the ground return for the near field."

Looking at Fig 16, the difference between perfect earth patterns and real earth patterns is considerable, though due largely to loss beyond the radials, perhaps.

Also see Fig 16 for the ground-plane at various elevations over perfect earth and over real earth. Close to the earth, the four radials are not effective in catching all the displacement current, but at 1.5-wavelengthelevation, the radials become much more effective and the difference in field strengths caused by poor earth is much less pronounced.

At 15 degrees, there is a 6 db difference caused by earth loss when the antenna is 1/8-wavelength high, and almost no difference when the antenna is 1.5-wavelength high. This difference must be caused by the earth directly beneath the antenna.

Best regards, Richard Harrison, KB5WZI

2745. Titanex Log Periodic Problem

I have just put up a Titanex LP12 Log Periodic antenna.
Unfortunately its SWR is between 2 and 3:1 on all bands 14-30 MHz.
Titanex is no help; they just say I must have put it together wrong.
The manual is mostly in German, with some rather poor translations to
English. The manual is self-contradictory regarding the element lengths.
Several email exchanges with them regarding this have also been unclear
and contradictory, so I suspect there is a language problem.
Has anyone put up a Titanex log periodic, and found a low SWR?
If so I would like to know EXACTLY how you set the element lengths.
The twin boom design introduces an ambiguity about where you measure
from where the half-elements are mounted on the boom.
Thanks!

If you look at them from the point of view of what is going on inside the
device, the terminology is consistent. In both cases, the cathode is
emitting electrons. It looks different on the outside because the
battery is providing power and the tube is using it.

I am using and have always used a larsen 5/8s (coil with long whip) and never ever had problems with it. In fact Ive the same one I bought 20 years ago and its still going strong. I currently have it mounted on a Lip mount in the hood (the little angle bracket one).

I used to use the Larsen Mag but it rusted out, and the coax was replace once, so after 20 years work and I figured it was time to replace it. And Im keeping my truck so the 3 little holes on the inside of the hood didnt bother me. I ran the coax through the fender to the Door cable cover. Poked a hole in that and ran the coax in and up the door/wind frame to the rig.

Works most excellent. So go Larsen. Mag if you have to but I would suggest the Hood Lip mount. Works is solid and if you need to remove it just some small rubber plugs will fill the holes and they wont even notice them I bet.

Source record: 131086

Ok, I moved out of the drafty narly room and finally was able to get one of the spare bedrooms after the kids are gone. In the drafty room I had a hole in the wall that went right out to a ground rod, total ground run of 4 feet to my bus bar that the rigs tied into. Its a single story house but the foundation is up a bit. The drafty room was a family room built via a wall in the garage (before I bought the house) so that room sat right on the slab.

Now the new room is up a bit and I cannot drill a hole through that wall (wife forbades it). I was however able to find a run because the room abuts the bathroom and they cut a Gigantic hole for the tub drain and I was able to bring coax/rotor in that way. If I go under the house I might be able to drive a Ground rod under there, but the 00 cable would run about 8-10 feet, instead of the 4 as before.

SO, options, as Ive RF floating around that I need to get rid of, Ive clean some up via grounding everything together?

That shouldn't be a problem (length). Use flat braid. If you have RF still put in a counterpoise 1/4 wave wire. Connect it to the back of ur rig and run it around the room. If its instide use insulated wire and remember it will be hot with RF so keep it away from living things and stuff that will catch fire.

All Hail Bush!

Reported today by James Risen of the New York Times:
"A U.S. intelligence (sic) official said yesterday that
an 'extensive analysis' of the audiotape conducted over
several days has convinced experts (sic) that the tape
'almost certainly' contains the voice of bin Laden."

Well, they are "almost certain" which means this could still take some
time....

Surely this is just an intermediate chapter of "Where's Osama bin
Waldo?" After-all, what was our mission a year ago - now stalled?
Now that we are pursuing our stalled mission of a dozen years ago (see
what it means that this is "going to take a while?") I suppose Jeb's
girls will be throwing their hat into the ring 10 years from now to
take care of the guy that went after their uncle. The cute girls will
undoubtedly be prompted off-stage by familiar faces of past failed
campaigns to utter "this will take time!" This family saga has all
the native intelligence of the Beverly Hillbillies - except Jed
Clampet knew how to maintain solvency and Granny could kick bootie.

Meanwhile [reported by noted Right-Whiner William Safire today] a five
time convicted felon is preparing a "computerized dossier on your
private life ... plus the latest hidden camera surveillance" [the
effete nabob Safire continued with further sobbing descriptions of
John Poindexter:] the "master of deceit is back again with a plan
even more scandalous than ... trading missiles with the Iranians." I,
for one, have to take notice in this appraisal by the conservative
Osama-huggers who get dewy eyed about rights. How about the rights of
more than 3000 dead?

The government too stupid? By themselves, no, it took quite a few
stupid people to put them in charge. This does not diminish any
American's right to be stupid, but neither does it elevate the
situation to institutionalize it so aggressively as does the
administration.

OR, to maintain on-topic discussion of antennas, were you asking why
no one has the smarts to have not yet figured out a way to "igniting
large sections of the atmosphere?" Well given the latest Challenge,

postponed from October to November (this will take time), soon to be postponed again - it is unlikely that correspondence from that source will enlighten us with an answer to this mystery (stupidity strikes wide and large). Fortunately we have others who can fill us in.

death to the terrorists,
Richard Clark, KB7QHC

I am looking for a good, clean working AH4 antenna tuner.

I am also looking for multiband verticals or vertical dipoles.

Please email me direct at theplanters95 at aol.com.

I used the "30 up and 30 out" for quite some time -- ground
mounted
with the 30 out about two feet off the ground. It was a
great
antenna for the space and facilities I had available. I
used
it on 80 thru 10 meters -- it got out on 80, but was much
better on the other bands.

Richard Clark wrote:
"Are you sure you are not mixing loss and destructive interference?"

I think not. Ground conductivity is assumed the same, either perfect or real earth. Path length difference causes the interference patterns. Lobes are less distinctive with loss but deployment is about the same.

The bigger difference in amplitude due to earth proximity is simply because only 4 radials don`t effectively prevent path return current through the earth at low altitude. So, there is more loss for the ground-plane at low altitude. At high altitude, the difference in coupling between the radiator and the radials versus the coupling between the radiator and the earth is more pronounced. There`s less coupling to the earth.

The ground-plane needs more radials for efficiency if it is to operate at low altitude.
B L & E, figured this out 70 years ago. Brown, of B L & E, was the inventor of the ground-plane.

Best regards, Richard Harrison, KB5WZI

2760. Re: vertical antenna question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-19 19:54:51 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <utl5o87s9dst3c@corp.supernews.com>
Source record: 131101

As the term is universally used, the efficiency of an antenna is the fraction of the applied power that's radiated. Once the radiation takes place, energy can be lost in absorption in the ground, but this factor isn't usually included in the "efficiency". So we generally read that the efficiency of a ground mounted vertical can be made arbitrarily close to 100% by adding an increasing number of radials.

Absorption of energy in the ground near the antenna, by means of induced currents, lowers the efficiency of the antenna and shows up as increased feedpoint resistance. In the case of a vertical antenna with a radial system, the loss can be considerable. As I've pointed out on another thread, however, the ground loss in the near vicinity of a vertical dipole is quite low, even when the vertical dipole is low. In contrast, the ground loss under a low dipole is high due to the heavy current it induces in the nearby ground. Consequently, a vertical dipole is inherently more efficient than a low dipole when both are mounted over the same quality ground.

Both antennas lose power from the radiated field as the signals reflect from the ground at some distance from the antenna. Particularly at low radiation angles, a vertical typically loses a great deal more than a horizontal dipole because of the different way that the vertically polarized signal interacts with the ground. And the effect of the ground is much more dependent on ground quality for vertically polarized signals than for horizontally polarized signals. But this absorption, far from the antenna, is generally considered as a separate issue and not included in the calculation of efficiency.

From "Electromagnetics", Schaum's Outline Series, 2/ed: "As the monopole radiates power only in the region above the conducting plane, the total radiated power is one-half that of the corresponding dipole." :-)

Scotty,
A ground of 8-10 feet shouldn't be too much of
a problem. You might see a bit of 'RF' on 10 meters
but juggling the length a little should stop that.
Compared to what you have now, what can it hurt?
'Doc

I was thinking same Doc, but over the years Ive had both Ground rods and heaven forbid no ground rods. But, never had big deal with RF and or Computers before hi hi. Been lucky I guess. Ill go ahead and drop a couple rods about 4 feet apart, then tie them with 0 or 00 copper wire and run one up to a bus bar on desk then tie stuff together. Agree on 10 meter thing, Ill see first.

I have a metal case on puter but boy does it leak RF as well as my DSL Line. Sheesh, going to wrap the lines in some Torroids and see if it cleans em up some.

Yup! No argument.
I was trying to use a step-by-step to describe it to some one who doesn't have a Time Domain Reflectometer handy<:-)) When I was working I used to be able to borrow the one from our department. That thing saved me a lot of time after our repeater antenna was hit by lightening. The idea was to just replace the antenna, but the TDR showed a short in the 7/8ths Heliax about 30 feet below the antenna connector.

The repeater is no longer here, but I have over 400 feet of bare #2 copper about 3 inches under the surface. There are 21 8 foot ground rods cadwelded to the wire.

Since that time, I've only lost one PlolyPhaser and a computer which did not share a common ground except for the house electrical ground. That was a little too long for the rise time on the strike.

Roger,

I was just wondering if you could explain the physical mechanism that causes a total re-relfection of power at the transmitter output terminals. This total re-reflection of power would require a total re-reflection of both V and I at the transmitter output. What do you think could cause a total re-reflection of V and I at the end of a transmission line? What prevents any component of V and I from entering the transmitter itself?

Most of us who don't have TDRs do much the same thing when we go
outside in the daytime and use our eyes to detect reflections using
that part of the electromagnetic spectrum commonly known as light.

If you feed that antenna at the top center, it becomes a top fed L and will work very well indeed on several bands. Check out Cebik's articles http://www.cebik.com/ltv.html and http://www.cebik.com/ltv.html

Mine is 51 feet on a side and always outperformed my GAP Titan.

Other than some weak long wave IR and a sparkle, my eyes don't emit much light. Please don't tell me that I'm half of a bi-static radar....people might get the wrong idea.

Steve, VE9SRB wrote:
"Roger, I was just wondering if you could explain the physical mechanism that causes a total re-reflection of power at the transmitter terminals."

Steve addressed Roger, but I`ll butt in uninvited. Steve quoted Roger: "But, 50 watts is reflected back in phase with the outgoing power (and is in phase---."

The electrical mechanism is a length of cable which results in a phase reversal. This phase reversal adds to the phase reversal caused by the original reflection. The total phase rotation thus makes the phase of the reflection reaching the transmitter terminals in-phase with the power emerging from the transmitter.

It is exactly in-phase because the author of the piece, Roger, made it up that way, which is the author`s privilege.

The reflected magnitude is less than that of the generator, so current must flow away from the generator and not into the generator. The reflected wave had its voltage and current placed out of phase by the first reflection. The re-reflection at the transmitter terminals places the re-reflected signal voltage and current back in-phase just like the voltage and current of the newly emerging power out of the generator. The line does this so as to not confuse the Bird Wattmeter.

Best regards, Richard Harrison, KB5WZI

I guess that circular polarization (CP) would have a loss halfway between vertical and horizontal (?). I notice that CP is often the 'forgotten cousin' of polarizations. Pet peeve of mine.

Scotty,
If your DSL line is giving you problems, the best
method of 'curing' RFI problems is to use a shielded
line from the outside box to the modem. Ground the
shield at the outside box and also use an AT&T #1611a
filter there (the 'S.W. Bell' part number is;
"AT&T 462-005-173-4", it's made to fit the 'box'). It
never hurts to have a 5 gallon bucket of torroids laying
around...

Message-ID: <HkDC9.338682$S8.6600110@twister.tampabay.rr.com>
Source record: 131118

Just read thru the thread that has been going on here for the last couple days, and find it most interesting. I thought I would chime in with my 6 cents worth (2 items at 2 cents each, my 2 cents worth with a multiplier - HI HI)

First, one poster mentioned the Army's instructions about a wire on the ground being viable. Here is a link in which the author discusses "grass mounted" antennas. I haven't tried it, but the claim is that it will get you on the air.

http://users.erols.com/k3mt/graswire/graswire.htm

Second, years ago in Massachusetts, I had the occasion to be working from a portable location in my old home town of Melrose, a Boston suburb. I didn't have the time or resources to get an outdoor antenna erected, so I just took about 40 feet of wire and ran it up the stairs to the second floor. It just laid on the stairs and the floor. I worked it with a tuner against a water pipe ground underneath the kitchen sink. I was working all over the northeast on 75 meter sideband each evening with acceptable results.

Third, 2 years ago, my regular inverted vee came down in a storm (Connecticut QTH). It was winter and I wanted to get on the air. I strung about 25 feet of wire from one room to the adjoining room, and with a tuner, worked it against the hot water baseboard radiator (as a ground). Worked as far west as Colorado and as far south as Florida with 5 watts on 40 meter CW.

The moral, sure, if you can, get your dipole up as high and in the clear as you can. If not, make do with whatever antenna you have or can jury rig. You will make contacts and have fun. In an emergency (Heaven forbid) or when nothing great is available, most anything metalic can be made to "take RF" and get a signal on the air.

The polarization of a circularly polarized wave rotates each cycle. So energy striking the ground when the field is vertical would result in different loss than when it's horizontal. The result would be that the polarization would become elliptical or, in some cases, nearly linear, after striking the ground.

See John Stanley, K4ERO's article in December 1976 QST for a discussion of practical considerations for ground radials.

If you can manage a 5/8 wave antenna (about 41 feet on 20 meters) you will get a lower angle of radiation than you will with 1/4 wave antenna. The antenna will be good in the lower bands as well. A suitable matching network is located at the base of the antenna to be switched in for each band you plan to transmit on.

Is the magnitude of the outflowing current at all affected by the arrival of the 'wrong way wave' ? Is the resultant magnitude of the outflowing current equivalent to any other explanation regarding the 'goesintas' and 'goesoutas' ?

Those pesky flowing electrons and holes (especially the holes!) refuse to wear name tags. It makes it so hard to know what is really going on... Maybe someone could measure the 'wear and tear on the carpet' (electromigration of a thin wire) to tell if '101 left' plus '101 right' equals something closer to 202, or closer to 0. Since electron flow has such low momentum, the answer must be towards the zero (Kirchoff would be happy).

Arie,

Pretty much same problem with Win2K. I solved most by reading the ini files, but it came down to the support files needing to be in a system directory in C: drive - my system files are NOT on drive C: and the matter of drive seems to be hardwired into the program.

You should look into any of the installer programs having a free version available for non-profit sites. They offer an alternative to huge readmefirst files.

He did say that "we have a good match" in which case the wave interference
pattern at the Z0-match point can cause a total re-reflection of power
at the transmitter output terminals. If reflections exist in the system
and no reflections enter the source, then all reflected energy is
necessarily re-reflected back toward the load. Reflected energy cannot
disappear or stand still.

Windows XP (Win2000, others ?) includes a free hidden IExpress program that
can be used to prepare an installation package.

C:\WINDOWS\system32\iexpress.exe
(you can make it into a shortcut)

I have a HI-Q antenna mounted in my unused ball hitch hole on my bumper with
a quick disconnect so I can remove the antenna to open the tailgate.

Did ya make sure to use some type of sealant or insulation around that hole
in the wall???? That would explain some of the draftiness!!!

It definitely needs to be mag-mount. There are a variety of times where the radio, and the antenna itself needs to be moved from vehicle to vehicle. My question is mainly from the standpoint of wanting peoples real life experiences with the particular favorite.

So... one vote for Larsen at this point.

Thanks,

Hmmm... will have to look at that as another possibility as a permanent mount as well as keeping a magmount for the portability aspect mentioned in the other response here. Both would need to be the best possible out there on the market.

Thanks,

They're fools if they really believe that. Heinrich Hertz showed, through
experiment, that electromagnetic waves can be reflected and refracted
just as light can.

Hi Jack,

It may, depends on the formulation used to make the "toroid."

The real answer is that your test would be more proof than any
conjecture and faster than this response. If it doesn't; then it may
be that you used the wrong formulation, not enough turns, or a choke
is not your solution. It may be rather difficult to distinguish
between these issues, but it is a start.

In other words try it and get back to us either way.

Hello Doc,

It should work on all systems from Windows-95 to Windows-XP.

Did you read the _ReadMeFirst.txt file about installations issues and
what to do when certain errors are logged ?

The 4nec2 standard version runs on all systems, including the older
ones.

The 4nec2X eXtended version, using hardware accelleration however
requires more recent hardware and garaphic-card drivers.

Let me know if you are not able to solve the problems.

Arie.

2798. resonance & impedance vs heighth?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-20 13:09:29 UTC
From: carkenord@juno.com
Message-ID: <4346b55e.0211200509.3f3392db@posting.google.com>
Source record: 131034

I built a one wavelength "rectangular" loop antenna with a design freq of 21.235 Mhz. This loop is to be used in a vertical position......IOW.....the 4-sided rectangular loop will "stand up".

As constructed, the feedpoint was 3 FEET above earth. When in this location, my Millen GDO indicated resonance at 21.240. This at the feedpoint.

Feedpoint impedance as measured with a Millen Antenna Bridge was abt. 60 ohms, at 21.240 Mhz.

I then raised the loop to its final operating position, which now has the feedpoint at about 16 feet above earth.

The GDO now shows resonance at 21.235 Mhz, and feed impedance as abt 42 ohms.

So in this case, raising the loop approx 13 feet caused the resonant freq to INCREASE by .095 Mhz, and the feed impedance to DECREASE by abt. 18 ohms.

I am pretty sure this was "normal" behavior, and was within expectations.

However, I wonder.......is it safe to make a "rule of thumb" from this?

As an HF antenna is raised above earth, will its resonant freq ALWAYS increase?

Will its feedpoint impedance ALWAYS decrease?

I tried the AH4 and found it to be horrible. Trying to get a random length whip to be effective using a so called antenna tuner just did not work. Antenna tuners don't tune antennas. Whatever you choose, go with a resonant antenna. I've used some of the other motorized antennas. Two brands just fell apart.

I now use the High Sierra HS1800DX. Those guys have mounts that you can use in the bed of the truck or put into your 2x2 receiver. Very professional looking antenna. They're not made in a garage. Performance with that type of antenna is very, very good. They also have lots of colors for the antenna. It's a first class system.

Roger Halstead wrote:
"Since that time, I`ve only lost one Poly-Phaser---."

My company had hundreds of radios around the world. Many had antennas at the highest points and often took direct lightning hits.

Our practice at VHF was to use folded monopoles solidly bolted to the tower top. If we couldn`t use a grounded antenna, we shunted the antenna with a short-circuit 1/4-wave stub at the antenna feedpoint.

We never had lightninng punctured Heliax nor r-f feedline blown transistors in the radios. We never used gas tubes or any other arrester on antennas or feedlines. Gas tubes were obviously superfluous for r-f circuit protection with our grounded antenna systems.

Heliax is a common-mode choke (inside) and a powerful impedance to the a-c component of lightning. D-C was shorted at the tower-top.

AM Broadcast stations in the medium-wave band, I`ve worked in, all had arc sensor/killers on the transmission lines. Coax lines were d-c isolated so that a relay d-c supply saw the space between coax conductors as an open circuit in its relay power supply. Any arc across the coax completed the relay power supply circuit, actuating the relay and momentarily killing the transmitter so it could not keep the arc alive. This is unnecessary with 2-way radios as the carrier is going to drop anyway.

MW broadcast stations have arc gaps across tower base insulators which never fire. The Faraday shield in the dog house takes the lightning hits.

Shortwave broadcast stations have arc gaps across the antenna feedlines at the plant entrance. These fire about as often as their medium-wave equivalents. Open-wire lines think they are common-mode chokes too.

I`ve used many gas tubes to tame surges on control, power, audio, phone, and data lines, but at r-f, other than radar, they are mostly superfluous.

Best regards, Richard Harrison, KB5WZI

Sorry to hear about the problems.

I tried overhere to install on drive D:\.

I would very much like to know what problems you got, because I
succeeded in this without any problems...

If you would let me know about the problems I can see what to do about
them, and, if appropriate, avoid these problemns in future releases.

Concerning the installer, maybe you are right. I once tried the
default microsoft installer, but using this required too much effort,
which I could better use in improving the software.

Furthermore to avoid that the installer changes a number of
uncontrolable and unreversable system settings/files, or replaces any
undesirable files I decided to do it the 'manual' way. (and it's
always nice to know what you are doing even when you don't understand
exactly...)

This way it's also possible to keep the zip file for the standard
version below 1.44 Mb so it fit's on a single floppy for all those
without the latest hardware and/or internet connections.

Arie.

p.s. thanks for your suggestion, I'll take a look.

Roy, W7EL wrote:
"Consequently, a vertical dipole is inherently more efficient than a low dipole when both are mounted over the same quality ground."

Antenna efficiency is as Roy said:
"---the fraction of the applied power that`s radiated."

Efficiency is usually the fraction the radiation resistance makes with the total of radiation and loss resistances.

Assuming equal heights for vertical and horizontal dipoles, seems to me the outlook for the horizontal is not that bad. An example where the vertical is twice as high as the horizontal is not all that bad for the horizontal. The vertical`s center is at the height of the horizontal.. See Fig 4A on page 3-5 of edition 19 of the ARRL Antenna Book. The solid line represents the horizontal dipole. The broken line represents the vertical dipole.

Advantage clearly belongs to the horizontal antenna, though this may be more effect than efficiency. It`s really effectiveness we need whatever the efficiency is.

How much gain can one get, claimed or otherwise, from an omnidirectional whip?

What would be the difference, radiation-wise, from 1/4, 1/2 and 5/8-wave whips?

For antenna gain info -- see URL:
http://www.larsenantennas.com/technical/basics.html

Its a matter of angle of radiation that gives "gain"
As you go from 1/4 to 1/2 to 5/8 wave antennas -- the angle of radiation
goes down -- thus gain.

See Auto and antenna illustration at the above URL.

For gain specs -- see URL:
http://www.progressive-concepts.com/36.html

1/4 wave -- unity
5/8 --- 3.4 dBi

Hi Arie,

Is your system on drive D:? I doubt it.

The simple solution is to remove all "C:" references from the hard code. This is poor practice when providing a simple root symbol "\" would allow more flexibility. Using the simple root symbol is poor practice too, compared to storing paths in an ini file (obviously, you only do some of them and THAT is the problem).

>Concerning the installer, maybe you are right. I once tried the

This only means you have passed this"too much effort" onto your user. In this day and age this is evidence of not ready for prime time, especially since free installers have been around for at least 5 years. That is one reason why I turned to coding in Java where the application is not dependant on peppering the hard drive with a handful of separate files.

New systems are on the shelves WITHOUT floppy drives and software delivery is either Web based or CDROM based.

Hi Danny,

Confusing text has been removed from my quote above to allow you to
observe your answer.

If you read the complaint:
> my system files are NOT on drive C:
You will observe that this is NOT covered in the readmefirst.txt file
because there are so many possible problems in a real world it is
impossible to anticipate them all in a text file. Further, this
complaint reveals a common problem of hardwiring presumed paths into
code for which there is no solution to be found in any readme or ini
file.

Ah Punchinello!

Speaking of wool...

Could you name another reflection that does not return power? You
have made a rather meaningless statement without numbers. Ever feel
the cool reflection of the sun from a shaving mirror? How about the
resounding crash of a wave against a bulkhead - think all that
returning water entered another dimension? Then perhaps your buddy
Lord Kelvinator pre-empted Sir Fig Newton's laws of motion?

Your questions still have all the romance of a civil service exam.
You probably can come up with some old wive's tale to match can't you?
I am sorry to say it would be hard pressed to match some of our civil
servants best efforts (after-all, with a single party hammerlock on
every house of government, our servants have yet to figure out a way
to pass a budget - much less a balanced one).

Hi All,

This is because those tubes are working (TR/ATR) tubes used to switch paths and isolate system components and are held partially ionized to speed up the switching action.

Lee,
I think your 'rule of thumb' is okay as far as
it goes, but needs to be taken at least one step
more.
Frequency does tend to rise as the antenna is
raised, and the input impedance does tend to lower.
But, there are limits. The resonant frequency doesn't
raise 'for ever', and the input impedance will tend to
'cycle', go down for a while then reverse and go up
again. That 'cycle' is sort of like a damped wave.
Big variations to start with, that dwindle to a steady
value.
Like any generalization, it's never always 'right',
just like any 'rule of thumb'...

My ground mat hides at least 0.5dBi gain loss due to the earth it
covers. This may hardly swing the meter; but given the dBi spread
across all the reported numbers above, 4.72dBi, it is significant.

>This difference must be caused by the

Hi Richard,

The difference must be caused by earth, certainly, but this does not
isolate it to loss.

Well, maybe you can help us out here. Can you give us an example of an
EM reflection that doesn't contain energy intrinsic to the EM fields?

Bob,

it was supposed to be very subtle irony. I agree, though, verticals are not high gain antennae, unless they are multiple wavelengths long, and the differences between one vertical and another will be cancelled out by some other positive or negative attribute.

Richard Clark, KB7QHC wrote:
"This is because those tubes are working (TR/ATR) tubes used to switch paths and isolate system components and are held partially ionized to speed up the switching action."

Yes. That is necessary for fastest action. Without such a speed up, the pulse would be gone before the gas tube fired. The way gas tubes are used to protect sensitive low frequency circuits is to slow the transient with capacitance and inductance giving the gas tube time to fire. In r-f circuits that is rarely an option. Selectivity can be used to limit the energy spectrum from a surge that protected equipment is exposed to.

Semiconductors are a good protection possibility for r-f circuits. These may be combined with slower acting devices to take the stress off the semi before it is destroyed in some cases. In other cases it is hoped the sacrifice of the semi was not in vain and that the next strike comes after protection has been restored.

Most gas tube protectors are too slow for r-f even if they were needed, and most aren`t needed.

Best regards, Richard Harrison, KB5WZI

I'm sure this will draw sparks, but it's my opinion that grounding to
cure RF in the shack problems is generally a waste of time. The real
problem is most likely your antenna and feedline setup. Either that,
or the antenna is right over your head...You mention coax and a rotor.
I assume you are running a beam of some type. I would double check the
connections, matching device, and feedline before bothering with a
ground. With an antenna like a yagi that is normally fairly well
decoupled , you should not need a ground connection to cure rf in the
shack. If you do, you have an antenna-feedline problem. All my yagi's
here are among the "coldest" antennas I run as far as RF in the shack,
and I use only simple gamma matches. My HF beam uses only a 1:1 coax
choke. I've never had rf problems with it, and haven't used a ground
at the rig so far. For some reason, the shield of your coax is hot
with common mode currents. That's what you "really" want to fix.
Improve the matching device, or add extra decoupling at the feedpoint.
IE: ferrite beads, etc. Adding ground rods is just a bandaid that
might or might not work. I battled rf problems for a long time when I
ran my old 730 and a henry console. The 730 is sensistive to rf
floating on the rig, feedlines if you use outboard mike preamps, etc.
Never once in all those cases was the problem the ground , or a lack
of one. Every single time, it was an antenna or feedline problem. Just
having rusty hardware at the feedpoint, baluns, etc, can cause this
problem for instance. Now, when I have or hear about rf problems,
grounding is the last thing I think about. I use no external "rf"

ground anymore, and haven't for quite a few years. And I actually have less problems than when I did. I've seen many cases where a ground to the rig makes things worse. MK

Hi Richard, All,

Gas tubes also have a considerable amount of wide band noise
following the event as the gas de-ionizes, which for radar systems
limits the detection of nearby targets (their being lost in an
elevated noise floor).

2829. HELP - rebuilding old AEA FSTV 430-16 antenna. ?coax used in matching loop?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-20 22:29:19 UTC
From: VE3EIE John in Ottawa <ve3eie@rac.caNOSPAM>
Message-ID: <3DDC0CBD.1050602@rac.caNOSPAM>
Source record: 131068

Hello everyone,

I need your help as I am rebuilding an old AEA FSTV 430-16 antenna
that came down in an icestorm and the only thing left to know about
is its coax "matching loop." The bit of coax used at the feedpoint
is about 10 inches long and has CATV connectors on it. It's gone bad.
I don't have impedance measuring equipment for those frequencies.

Would anyone have information on the coax needed?

AEA was bought by Timewave so I've looked at their site already
and found nothing but did drop a line to their service department.

The only information that I have left on this antenna comes from
the end panel of the original shipping box and is as follows:

Advertising bits: "The antenna of choice for the ATVer.
Also great for DX-chasing at 432 MHz and
satellite Transmit/receive at 435.9 MHz."

Frequency: 420 to 440 MHz
Gain over dipole: 14.3 db
F/B ratio: 20 db
Beam width: E-28, H-32
VSWR: 1.3:1 or better
Power handling: 250 W.

Thanks for any assistance,
John

It is not used to overcome the farady rotation but for ham radio it is used because they spin to stabalize the position of the satellite. Comercial sats use left and right circular to pack more transponders on the sat in a given frequency range.
The odd and even chanels are reversed circular from each other. This gives an aditional 20 db or so adjacent chanel rejection.

Hi Jack,

An alternative is to use a more flexible (smaller?) cable that is
short enough (connectored at both ends of course) to loop through
several more times (you gain with the square of the number of turns,
so this is payback big time if you can). Don't worry about cable loss
or connector loss unless you are pouring power to it and would risk an
arc-over due to smaller cable dimensions. Try this as a test, not a
permanent installation (unless it works really, really good).

Let us know either way.

> cousin' of polarizations. Pet peeve of mine.
>

The loss between a circularly polarized wave and a linearly polarized wave
is a function of two things:

1) The axial ratio (AR) of the circularly polarized wave. (The ratio of the
vertical pol. component to the horizontal pol. component)

2) The polarization purity of the linearly polarized wave.

All things being perfect, AR=1 (0 dB), and the linear wave being purely
linear, there is a 3 dB mismatch loss between a circularly polarized wave
and the linearly polarized wave. As the AR varies,the loss may be less than
or greater then 3 dB as a function of the alignment between the two waves.

As Roy pointed out, a circularly polarized wave reflects off a lossy surface
with an elliptical polarization. For a perfectly conducting reflector, the
sense of circular polarization changes after reflection. I.e, a RHCP wave
becomes LHCP and a LHCP wave becomes RHCP.

CP is not commonly used in terrestrial systems, although there are some
specialized applications. It is exclusively used in satellite transmissions
to overcome faraday rotation in the atmosphere.

W.G Ewald <wgewald@att.net> wrote:

>Was Poindexter *convicted* on any charges?

According to the reports I've read in the media and on the Web, Poindexter was in fact convicted in court on five charges (conspiracy, two counts of obstructing Congress, and two counts of making false statements) on April 7, 1990.

The convictions were later overturned on appeal. As I recall (and I may have the details wrong): Poindexter had been granted immunity from prosecution on the basis of his testimony when he was compelled to testify before Congress. This is a legal way of requiring someone to admit to actions which may be possibly criminal, as it removes the necessity for invoking the Fifth Amendment against self-incriminating testimony.

His trial was held (later) based on the testimony of people who had witnessed his actions and the events of the Iran-Contra scandal. It was on the basis of this testimony and related evidence that he was convicted.

The Appeals Court ruled that evidence introduced at the trial was "tainted" by the fact that the witnesses who testified against Poindexter had had, or might have had access to his testimony... and that this was a form of (indirectly) compelling him to testify against himself.

In effect, Poindexter was released on a legal technicality (the use of inadmissable evidence, due to a violation of his Constitutional right to not testify against himself). It's exactly the same technicality used to block the prosecution of suspects who made coerced confessions, or weren't read their Miranda rights before confessing, or who were questioned by police after insisting on the presence of a lawyer, or whose homes were searched on the basis of a search warrant gained by the police on false pretenses.

I gather that the prosecution chose not to attempt to re-try the case... presumably because they were unable to amass sufficiently-convincing testimony from those witnesses who could be shown _not_ to have read or heard Poindexter's testimony before Congress, either directly or indirectly.

The news archives I've read indicate that Poindexter and all of the other significant "players" in the Iran-Contra scandal were pardoned by President George E. Bush some time after this.

Always nice to know people in the seat of government when you find
your ass in sling. The quote above comes from the horse's, uh, mouth:
http://www.hpoindexter.com/jmarlan.htm

This, in a way, reminds me of that sterling representative of the
Marine Corps, Ollie North one of the world's greatest under-achievers
who certainly had an exaggerated self opinion (now for sale to the
highest bidder). If the name seems familiar, he was the pot plant
sitting next to a lawyer during Iran-Contra investigations. Again,
with this ass in the sling, his friends (and they weren't to be found
at the base Officer's Club) bailed him out a la Cosa Nostra. If he
had gone to work across the Potomac, his ass would've been in a
tourniquet.

Something tells me neither of these patriots have the slightest
inkling about how to design an antenna capable of "igniting large
sections of the atmosphere" But just utter this phrase within 1000
feet of Congress and you will undoubtedly be stormed by 500 odd
wannabee patriots throwing money at you. And failing that, apply for
a Government Grant to build them for Saddam. The money should be
flowing freely soon and no one seems to care where your business goes.
It would be no harder than selling and shipping missiles to Khomeiny
(I a tol' ya!).

The irony of this "igniting large sections of the atmosphere" is found in this is technology we developed following the first failed attempt to take out Saddam. HAARP was thought to be capable of "igniting large sections of the atmosphere." The research folks in our armed forces shushed us with calming tones about investigating the magnetic lines and their effect on solar radiation (not just sunshine). It was speculated that if they could modulate those lines (through sheer brute force power) they could also modulate the natural background radiation levels. If they could do that, they could also measure that modulation and correlate it into geophysical structures - something like a CATSCAN for the earth. This lead to further discussion as to how this CATSCAN could reveal subterranean bunkers on the other side of the globe. Does anyone really believe we smashed the tunnels of Afghanistan simply by waiting until someone stood in front of them waving a flag?

The folks that get things done are wearing a uniform. However, this is not to be considered for too long or too deeply by the Right Whiners. To their standards of citizenship, service in uniform during time of war is NOT patriotic enough. In today's news (Curt Anderson, AP) comes reports of how retired WW2 and Korean Veterans have been denied their life-long medical care, because "it wasn't put in writing." The judge that upheld the Defense Department position stated (with crocodile tears) he "can do no more than hope Congress will make good on the promises made in good faith." Well, after seven years you might think so - - - if you had ever worn a uniform that is.

Message-ID: <arh812$850$2@knossos.btinternet.com>
Source record: 130928

It is inadvisable to trust resonant frequency measurements made at the feedpoint by a GDO. An article in a magazine, even if approved by the technical editor, would be shot to ribbons.

It is far, far more reliable to use one of these new-fangled, hand-held antenna analysers and look for minimum input resistance associated with zero input reactance. And even then it could only be guaranteed to be in the right HF band.

The affect of height above ground on the resonant frequency of vertical loop antrennas is very small until the bottom of the antenna is only a foot or so above the ground. It depends on soil resistivity and permittivity and on the size of the loop.

When soil resistivity is very low, at very low heights, compared with the natural resonant frequency, the resonant frequency may increase. But when the soil is poor and has a high resistance, the resonant frequency may decrease with decreasing height.

Since what happens is within the near field of the loop anttenna it can be modelled as two coupled circuits. The coupling between antenna and ground is of two types - inductive (transformer) and capacitive. For an HF antenna the whole thing is frequency dependent between LF and VHF. Measurements at one frequency are meaningless.

In the presence of other more serious abberations of which you may be unaware the relatively small change in resonant frequency with changes in height of the whole antenna are inconsequential. No conclusions or 'rules of thumb' can be drawn from them.

On the other hand, as someone else has pointed out, the decrease in resistance with increasing height is what is normally experienced. As the antenna nears the ground larger currents are induced in the soil and soil loss increases. So the measured input resistance increases. In fact the loss in radiating efficiency due to ground proximity can be accurately estimated very simply from the high and low input resistance measurements.

Some idea of the magnitude of the effects can be gained from program MAGLOOP4 down-loadable in a few seconds, run immediately, from website below. The primary purpose of the program is to aid antenna design and construction but the change in resonant frequency versus very low height is illustrated by the change in tuning capacitor setting needed to maintain a constant resonant frequency.

The program makes no pretence of being accurate in those particular effects. But from crude measurements made in my own back yard, with the local guessed-at low soil resistivity, at 1.9 MHz the program's results are in the

right ball park. No great importance should be attached to them. For example it would be a complete waste of time trying to predict soil resistivity from the change in resonant frequency as a loop antenna nears the ground, checked by GDO or not. There are much better ways of doing it. ;o) (Note smiley).

Play with MAGLOOP4 It is usable up to loop perimeters of 1/2 wavelength.

Yes, I'm soaking in it (CP). Lots of fancy antenna modelling SW tools that
do not (easily) handle "CP". Pet peeve. Sigh...

Certain (rare) radar applications use CP with appropriate feeds (two).

Other systems use CP/EP when they can't predict the orientation of the
receive antenna (some commercial FM broadcasters ?, others ?).

DirecTV (and so on) is probably the #1 application right now. GPS #2 ?

Message-ID: <li6dnUaMTK8QpkGgXTWcrg@comcast.com>
Source record: 130937

Lee,

I knew there was a graph of impedance vs height in the ARRL haandbook. Unfortunately, nothing is simple. However, for a horizontal dipole, the impedance at 0.2 wavelength is about 65 ohms, at 0.35 it is 95 ohms, at 0.6 it's 55 ohms, and at 0.85 it's 85 ohms. Now what happens below 0.2 depends on whether you have poor ground, or perfect ground. With perfect ground, at 0 height the impedance is 0. With poor ground, the impedance at 0 height is 90 ohms.

I don't think resonance changes with height once the capacitance to ground becomes small.

BTW. You might try feeding one of the bottom corners, with the center conductor of the coax going to the vertical wire, and the shield to the horizontal.

Tam/WB2TT.

2849. skin effect

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-21 02:21:54 UTC
From: Mike Coslo <mcoslo@adelphia.net>
Message-ID: <3DDC4333.6020001@adelphia.net>
Source record: 130938

In prepping my magloop for service, I was planning on running some steel wool over the loop, then painting it to seal it.

This got me to thinking. If the surface is tarnished, will this really make for a higher resistance due to skin effect, or will (what I really think happens) does the current just run a tad deeper? I could experiment, but that might take a while.

Secondly, if I were to attach the contacts to the antenna on the inside of the tube, would the skin effect cause the outer portions of the tube to contain the signal, as all the signal skins to the inside?

I hope these questions do not brand me as hopelessly dense.

Much as I dislike some of the current state of things in amateur radio, we live in the 2000's not the 1950's. We have to deal with the current reality, bad as it might be. Returning to 1952 is not going to cure the problem. We need to pull together as hams and do things without bugging the FCC for everything. We used to do that.

Why not just drop the archaic code requirement, beef up the theory
requirements and get hundreds of new, excited members tomorrow? That'll be
the biggest shot in the arm the hobby has seen in decades.

I would suggest somethig rather different.

Take out the code requirement, and put in the test some DSP questions
(how to make filters, equalize volume, remove noise, and modulate in
phase, frequency, quadrature, etc) as well as more advanced circuit
design.

The code requirement is just silly.
Code is just one of the many ways to encode a signal, a way that
happens to be possible to do by hand. But why bother with it?
That it is useful in emergencies is a ridiculous thing - if your
transceiver works, you might as well talk into it, so also general
SWL, and not only hams, can understand your transmission.
Instead, with the increased ease with which signals are digitized,
DSP should really be required knowledge.
I mean, it takes so little nowadays to feed the signal into an audio
board
or better A/D converter, and then start doing things digitally...

In fact, consider this: DSP should be required because, in case of
emergency, you hook up your PC/laptop audio board to the radio, and
there you go,
modulating any way you want...

Code is what keeps me getting a ham licence.
I just don't suffer fools gladly, and the code requirement is foolish.
If I want to waste time, there are many more pleasant ways to do it.

Cheers!

Peter

Oh and one more thing: I think it is incredibly funny that in a
country where you can get a driver's licence without knowing how to
operate a stick shift, you cannot operate ham without knowing code.

There, now flame me.

You're wrong, of course. If you look at amateur radio from the view of a non-involved historian, the only regulatory change which had a significant statistical impact was the advent of the Novice license back in the early 50's. As originally envisioned and structured, Novice was an incredible smart regulatory move, perhaps the last smart thing the FCC did for the health of the Amateur Radio service.

Other than that, changes in licensing requirements have served only to generate sales of ink, to excite the excitable minority, and to give the Unabashers another reason to cancel their ARRL membership or to buy a life membership. No other impact is evident, and won't be after this current curve in the regulatory road. Hams will still be hams, and the excitable minority will get excited all over again. In about 2012 we'll be awaiting the next "restructuring" plan. Yawn.

Hi Mike,

Your natural sense is already leading you in the right direction. The
tarnish only exists as a problem when it comes to a point of contact
with another conductor (next section of the loop presumably, or the
cap).

Secondly, attaching to the interior means the RF path will simply flow
along the inner surface to follow your cable back outside through that
puncture in the RF shield (how the cable got inside in the first
place) and complete its business in the usual fashion. However, as
the currents are huge, why would you add non-inductive length?

I am trying to finalise dimensions and matching for a full size 20 meter horizontal dipole bent around to form a compact square antenna rather like a VHF Halo.

Modelling with EZNEC Demo suggests a fairly omnidirectional horizontal pattern and little reduction in performance compared with a regular dipole. However the feedpoint impedance does drop significantly - to about 9 ohms or so. I have changed element to a two-wire folded dipole and this brings the impedance up somewhat to about 30 ohms.

My question is whether shorts placed across the folded elements at some point in from each "end" will increase the normal 4:1 transformation ratio to give me a near 50 ohm match? How does one caculate where these shorts should be? I dont think I want to go to a three wire folded dipole!

Ban everyone who is not 100 percent in accordance with your views . Who the heck would you then post with?

Get real, everyone is entitled to their opinion.

Some where between you and him is probably a reasonable solution. I have noted that of those who got a ticket with little work, many are not renewing. A thing only has value when we have to work for it, unfortunately the ticket no longer requires much effort and has no real value to the recipient.

Still stuck in my mind is sweating before a steely eyed FCC examiner, drawing schematics, sending, and receiving code. Did I enjoy the process? Nope! but I did enjoy being able to count myself among a group of fellow hams that had gone through the "baptism of fire".

I don't care a wit that some folks have 5wpm licenses, You have yours and I have mine. I feel mine is worth more, but that is my opinion. Your mileage may vary...

Allow others to have their opinion, and now that the horse is dead you may cease the use of the whip.

IMHO,
Requiring A/D knowledge is equally as silly as requiring knowing code.
A compromise test of all the various technologies is clearly the logical
way to approach licensing/testing and they attempt to do this to some
degree. But technology is changing rapidly and the wheels turn slowly.
I think we are at a point where a ham should know what A/D means even
if its only picking out the correct words on a multiple choice test.
But hmmm, isn't that basically what the code test is?

Ranting off from a recent thread on r.r.a.a. one would get the
impression that knowing the brand names and specs of current products
(the Hamstick thing) is more important in making a 'good' ham.

The League is pretty much in control of testing and licensing these days
and I'm of the crowd that thinks they are doing everything bass-ackwards

and ultimately alienating radio folks (both new and old) from their organization in favor of whiz-kid technology. I don't desire things to stay quagmired in the 1950's but I don't see the need to overwhelm the bulk of the ham community with articles that are better suited for an IEEE publication. If, back in the 50s, they published *ONLY* SSB stuff, the rank and file membership would have tossed in the ARRL towel...much like the situation we see today. QST is the League for most people and basically it (they) have become nothing more than another modern electronics magazine publisher, not a mouthpiece for amateur radio as a hobby for all age groups.
(Apologies to the CBers and SWLs that I'm cross-posting to)

Great gobs of bovine excrement, the license is simply insufficient
motivation for you to learn code. The "suffer fools" nonsense serves only to
cover up your lack of motivation. Learning anything is simply one more
exercise in broading one's life experiences.

<snip>

We now interrupt this boring thread where ham's bicker yet again about
licensing for a bit of light entertainment.

Community Service

One day a florist goes to a barber for a haircut. After the cut he
asks the barber about his bill. "I am sorry, I cannot accept money
from you I am doing community service this week." The florist is
pleased and leaves the shop.

The next morning when the barber goes to open his shop; there is a
thank you card and a dozen roses waiting at his door.

Later a cop comes in for a haircut and he also goes to pay the
barber, and the barber replies: "I am sorry I cannot accept
money from you. I am doing community service this week." The
cop is happy and leaves the shop.

The next morning the barber goes to open his shop; there is a thank
you card and a dozen donuts waiting at his door.

A Democrat comes for a haircut and when he asks the barber what
he owes, the barber replies: "I am sorry I cannot accept money
from you. I am doing, community service this week." The Democrat
is very happy and leaves.

The next morning when the barber goes to open his shop, a dozen
Democrats are lined up waiting for a free haircut.

: The next morning when the barber goes to open his shop, a dozen
: Democrats are lined up waiting for a free haircut.
:

A first grade teacher proudly proclaimed to her class one day that she was a liberal Democrat. She asked her students to raise their hands if they were liberal Democrats as well. Not really knowing what a liberal Democrat was, but wanting to be like their teacher, most of their hands flew up into the air. There was, however, one exception. A girl named Lucy had not gone along with the crowd. The teacher asked her why she had decided to be different.

"Because I'm not a liberal Democrat" she replied. ''Then, what are you?'' asked the teacher,

"Why, I'm a proud conservative Republican," boasted the little girl. The teacher, a little perturbed, asked Lucy why she was a conservative Republican.

"Well", she said, "I was brought up to trust in myself instead of relying on an intrusive government to care for me and do all of my thinking. My Dad and Mom taught me these things, and they are both conservative Republicans, and so now I am a conservative Republican too." The teacher, now a little embarrassed and maybe even just a bit angry, said, "That's no reason! What if your Mom was a moron, and your dad was an idiot. What would you be then?" The teacher paused, a bit smug, certain that she'd put the girl in her place, and slowly let a sly smirk creep across her face.

"Well, if that were the case", said Lucy after a moments thought,"then, I suppose I'd be a liberal Democrat."

Hmmm, ever consider that maybe this is one more way of relieving Saddam of some of his stash? We've heard the tales about Russian mafia selling him several loads of phony uranium for millions. So sell him an atmosphere igniter!

Seven nice steps to DESTROY and KILL ham radio. Only several fanatics would stay. How would you like to be re-tested for your driving license every year ? Or to be subject to regular tests from the law codex under the penalty of losing your citizenship ? BTW, do you have a written permission to use the "trademarks" Wouff-Hong, Rettysnitch and Uggerumph ?

God save the hamradio !

CP is used for both purposes. If the satellite wasn't spinning, you would find - as moonbouncers do - that CP is still necessary, to overcome Faraday rotation of the plane of polarization as the signal passes outward and inward through the ionosphere.

(CP is not used for moonbounce on the 'yagi bands', 432MHz and below, but that is for other engineering and historical reasons.)

>> CP is not commonly used in terrestrial systems, although there are some
>> specialized applications. It is exclusively used in satellite
>transmissions
>> to overcome faraday rotation in the atmosphere.
>>
>> Steve VE9SRB

CP is extensively used for FM broadcast (in Britain for sure, and probably elsewhere) in order to minimize cross-polarization dropouts, especially to mobile and portable receiving antennas. These antennas are likely to be using slant linear polarizations, and also the most likely to receive signals via reflections that change the transmitted plane of polarization. CP always suffers some loss when received by linear-polarized antennas, but it's never totally 'wrong', as linear-to-linear can sometimes be.

I might agree if the theory questions were "fill-in-the-blank" and
"draw-the-schematic", rather than multiple choice - where the answer is
right in front of you. This would help ensure that the person has some
actual knowledge rather than just having memorized a few answers from a
test prep book.

In reality, your proposal would not attract any significant quantity of new
hams because it would make the test harder than it is now. In today's
"instant gratification" mindset world, many people want every thing "now"
and don't want to expend any personal effort to get it. That's why the code
element is constantly being complained about by so many...

> years.

I tried the IEXPRESS.EXE But this does not seem to work on W-95 and/or
W-me (on which I created my 4nec2). If you have any other free, and
EASY to use, installer references, I would very much like to know.

> New systems are on the shelves WITHOUT floppy drives and software
> delivery is either Web based or CDROM based.

One of my targets with 4nec2 is to keep the package/executable as
small as possible, to allow it to run also on not so state-of-the-art
systems.

That's also why it's free, to support those who don't have lot's of
money to spend on modern computer systems or the latest commercial
modelling packages.

Thanks, for the feedback,
Arie.

The current will take the path of lowest impedance,
i.e. it will concentrate on the outer surface of the
conductor. If the "tarnish" is a lossy conductor it will
absorb a little energy, so clean the loop with steel wool
until it gleams, remove any trace of oil with methylated
spirits, dry with a CLEAN cloth, and immediately spray with
INCRALAC - This is a lacquer developed to prevent brass and
copper from tarnishing. I first read this tip years ago in
one of the MIT Radiation Lab series that were published not
long after World War 2 to "reveal" the secret materials,
components, systems, etc developed during the war.

MIT found that this gave the highest Q factor for
cavity resonators - far higher than using silver plating.
>
>Secondly, if I were to attach the contacts to the antenna on the inside
>of the tube, would the skin effect cause the outer portions of the tube
>to contain the signal, as all the signal skins to the inside?

Doesn't matter where you make the connection, the
current will head for the lowest impedance path (the outer
(Conducting) surface as fast and directly as it can.
>
> I hope these questions do not brand me as hopelessly dense.

Not at all. You are only dense if you fail to ask
the questions.

I've been asking questions for about 70 years now,
and am still learning something new. My approach is
basically "If it works, find out how, if it doesn't, find
out why."

If the connection is to the inner surface, the shortest path to the outer surface is along the inside to the nearest opening, then out. This might be a short path or it might be long. If the path is long, it'll add substantial inductance and, in the case of a small loop, unnecessary loss.

Hi Chris:

Years ago, if my memory is correct, Cushcraft made a halo antenna for 20m as well as the higher bands. You could make "Christmas tree" of them from 20m to 2m. Anyway Cushcraft and most others who make halo antennas use a gamma match on them just for the reason you have found. I don't know of any of them that are direct feed.
You could also try a hairpin match, or a delta match, but both of them will require a balun as they are balanced matching systems. The gamma match is an unbalanced feed system and doesn't need a balun and you could go back to a single wire design.

This brings a question to mind. If you uses copper tubing for a tank
coil and don't flatten the
ends when connecting it in the circuit, will you have any less loss?
Will rf current flow on the
inside of the tubing as well as the outside thus reducing skin
resistance or will it only flow on the
outside?

Jacques, ON5MJ wrote:
"How to avoid that radioamateurism becomes CB with 100 watts?"

"The government that governs least, governs best" is a reasonable proposition.

Licensing would not be needed were there not interference in uncontrolled use.

Egalitarians insist on equal rights limited only by possibility of serious harm.

CB with 100 watts for everyone could be handled with cautious regulation and enforcement.

Best regards, Richard Harrison, KB5WZI

Heh.....tubes?? Do you know how tough it is to get certain tubes this day and time? (and I'm sure you DO know) I'm restoring several boatanchors and have spent more time searching out certain tubes and caps (admittedly ones matching the look of the originals) than I would ever get back out of the rigs. 'Course, I don't plan to SELL the rigs...but use them.

Also, those requirements would drive a large portion of the HF operators out of amateur radio....as well as allow the FCC to justify selling off additional freqs. (technical competence would no longer be there....not "state of the art."). I can think of exactly one person locally who uses homebrew gear (a General class, not Extra, too).

Motivating people is what needs to be done...hard in this "I wanna" world. Heck, I have people ask me why I work so hard.....couldn't live with myself if I didn't give something my all. If you can figure out a way to motivate those interested in the hobby and make it worthwhile (i.e., flaming someone who is attempting to enhance their knowledge doesn't help), then those with an interest will come. Hear someone new that isn't doing something 100% correct? Offer counsel and advise...don't blast. He or she may not know the diff., so lead....don't shoot. Don't disparage...most anyone can be trained (ok, there ARE exceptions!).

BTW, I'm one of those "useless" no code techs. I have NO problem with having to learn CW for HF privileges, either (which I am currently doing....taken awhile, tho).

Nomen Nescio wrote:
"The hobby has become like playing pac-man on the computer; it`s entertaining but of little value."

Amateur radio is forever changed. Wireless is not an exciting novelty when everyone has a cell phone.

As a disaster service, amateur radio has forever lost clout because of cell phones and plenty of well equipped media.

Amateur radio never had an everyday serious function. That is prohibited by law. Any serious function must be handled by other communications services which can accept money.

Amateur radio is good as free communication for hike and bike fund-raisers.

Amateur radio as it was can`t be resurrected.

Best regards, Richard Harrison, KB5WZI

Chris,

I agree with the gamma match idea, but there are simple ways to get a usable match. First, 30 ohms is not bad; that is an SWR of 1.66. Once you go through some lengths of coax, you may end up with 1.5. Since you have a folded dipole, you need a 1:1 balun.

To match 9 ohms, use a 1/4 wave section of 25 ohm coax, made up of two pieces of 50 ohm coax in parallel. The SWR of the matching section will be 25/9=2.777. The impedance at the end of the quarter wave section will be 25x2.777= 69 ohms. Not bad. The SWR on the 50 ohm feedline will then be 1.38:1.

There is a section in either the ARRL Handbook, or Antenna Manual that tells how to use short combinations of 50 and 75 ohm coax to match any reasonable impedance to 50 ohms. Being in ZL, that may be a problem.

Actually, one should allow hams only to run equipment that they build and also
that equipment should meet reasonable technical standards (using REASONABLE
standards for homebrew.) If this means that the operator needs to build a
semiconductor 100W transmitter, then so be it!!! :-). This would certainly tend
to keep the 500W+ equipment less common, and those with the technical
expertise and discipline will more likely be those who have the equipment.

There'd be a few more hams with RF burns, but many more would really know how
their equipment works, and act more like hams than extension of CB. You'know
that CBers buy their kW linears also, even though illegally.

Rather than 'morse code', it'd be better for Hams to be well versed in the more
interesting modulation techniques of the current and future times. People who
are interested in 'quaint' history or interested in slow speed (but narrow-band
and long distance) transmission will continue to use morse code.

Increase the technical standards to a minimal level of COMPETENCY and not
memorization, while restrict access to the code bands to those with code
endorsement. Restrict access to complex modulation bands to those who
have the highest TECHINCAL expertise. In some cases, there'll be people with
both sets of permissions... Keep much of the VHF/UHF spectrum for the
communicator class of hams (e.g. those who buy their store-built equipment),

but reserve ALOT of space for those who take the learning part of the hobby seriously (high-end technical endorsement.)

If you really want to increase the Ham ranks, and improve people's knowledge
and skill at the same time...

Have a monthly operating contest where the winner gets $5000.
Have a monthly design contest where the best project gets $5000.

After winning, you would have to sit out for 2 years so others could
benefit.
The FCC could fund this using the revenue from the spectrum of ours that
they're selling to the cellular crowd and other big lobbies ;-)

Hmmm.... I had a license with code requirements (many years ago), but I also
have problems with certain kinds of motor skills. It isn't impossible, but I do tend
to find the competency of 100W+ CBers who happen to have ham licenses to
be disappointing.

My biggest frustration now is the use of SOT type packages for my RF design, but
I am working through the issues, and learning how to deal with the technical problems.
I suspect that much of the ham hobby is being supressed by the commonly available
parts technology (and at UHF+, the needed smaller dimensions.) However, from a
time and 'exclusive club' standpoint, I suggest that the competency of 95% of the hams
would be quite insufficient to build and fully understand their equipment.

This is akin to a brutish physical skill overwhelming intellectual comptency. Morse
code is only a brutish, anachronistic (most of the time) skill (which is problematical
WRT poor fine motor control.) It is apparent that some in the ham community
are compensating for lack of sufficient mental skills by making it exclusionary based upon
physical skills.

Good idea! Or at least build SOME gear....antenna, interfaces, preamps, etc. Heh....I'd hope that restoring BA's would count <<grin>>. Saddest thing I've heard, what with all the "CB" insults shouted around, are those who could contribute to the hobby leaving for other hobbies. At least those who TRY to bring others into the hobby will be doing more than a thousand complaining about the "newbies." NO ONE can ever again be a 20wpm extra licencee (i.e., passed 20wpm to get their ticket). Don't hold it against those trying to enter the hobby, as, internationally, CW is going away as a requirement. Make CW a point of HONOR, something to achieve, not a point of division!! (i.e., not an insult; "you no-coder." Make it a complement, i.e., "hey, you know CW, come on down to the CW only areas and have fun!" "Don't know CW? Why not try, we have fun on the special parts reserved for CW")(and, no, this won't work for everyone....of course. Some folks have no honor...right, Worf?)

Gary, K4FMX wrote:
"Will rf current flow on the inside of the tubing as well as on the outside---?"

Not as well because the outside is larger than the inside. Not only is there more surface outside but there is less inductance. See Terman`s 1955 "Electronic and Radio Engineering" page 21.
"It is to be noted that some of this flux exists within the conductor and therefore links with, i.e., encircles, current near the center of the conductor while not linking with current flowing near the surface. The result is that the inductance of the central part of the conductor is greater than the inductance of the part of the conductor near the surface---."

This is so even in hollow conductors. The smaller the radius, the higher the inductance.

It took a bit of work to get 4nec2 running, but it is well
worth it. I am a beginner at antenna modeling so keep that in mind,
Here are my impressions of 4nec2 and other demos I have tried. The
editor is not as easy to use as NECwin+ but the demo has run out and I
can't justify buying NECwin+, on my retirement income. The demo for
EZNEC in my opinion is useless and The editor for entry seems to me to
be poor. Not a good way to try to sell a program. Judging from the
demo I would rank EZNEC a distant last place. All three programs are
not very user friendly. You need to learn quite a bit about the NEC2
to do much with any of them. NECwin+ is the easiest to use for a
beginner. Their 30 day trial is useful for learning, even if you
decide you can't justify the price.
I found I could change the file extension of the models I had
written in NECwin+ from .inp to .nec and open them in 4nec2. 4nec2
has the best set of sample models by far and you need them to figure
out how to program the deck.
I can't print patterns on my Laser Jet but this is mentioned in
the documentation and it works fine on my color printer.
The windows in 4NEC are too small. You can't see the entire
title of long file names for example and they don't scroll.
If 4NEC2 had a better editor and entry system and better
documentation it would blow the others out of the water. 4NEC2 has
better graphics and plots with more information. I think it produces
the most professional result.
I am very happy with 4NEC2 and I can't thank the author enough,
for giving me such a fine program.

"Green Peace won`t stand for the poisoning of barnacles."

I hate barnacles. Everybody aboard used to have to turn-to scraping barnacles off the bottom of my ship in dry-dock except the steward`s mate. He claimed it was discrimination to nake a black guy scrape barnacles! So , there he sat watching all the officers and enlisted men except him scrape barnacles. We had to finish fast in war time. Pretty smart!

Isn't it a real paradox? The smarter and more beautiful the radios, the
dumber the hams who use them! :-)

Ham radio is now almost an endorsement on CB, rather
> than having to REALLY know (not just remember) something appropriate for
> the current world.

I certainly have no problem agreeing with this, although it really has
little or nothing to do with Morse code on ham radio. You can always use
a keyboard to send if you can't physically handle a manual key or
paddle. I may go to one of those due to arthiritis myself one of those
days. But a computer program does a really poor job of copying, as far
as any I;ve been able to evaluate shows. That will probably change if
some of you more computer literate souls choose to keep working on it.
Looks like you'd rather just dump the whole mode. That I don't
understand. I do understand why some people don't like th emode, and I
can appreciate that. There are things I don't like, too. I have no great
love for Morse code(despite the rantings of some of the more rabid
anticoders who post here), but I learned to respect it for what it is
and appreciate it for what it offers-the most basic, simple, easily
implemented mode of radiocommunications yet devised.

Does that mean I or any other CW supporter would in any way advocate
use of CW -at any time- to the exclusion of better more efficient modes?
Of course not, again despite the rumblings of some anticoders posting
here. I, and most other code supporters, routinely use advanced digital
modes, some of us use them more than CW. Again, that does nothing
whatever to diminish the qualities of Morse code. Some of us understand
the mode well enough to consider it to be a valuable asset to ham radio.
If you don't, that's certainly your privilege.

Hank,

In the long run, I don't think you will be happy with any of these. If you don't want to put up a full size beam, I would investigate two element tribanders like the Hygain TH2. This thing has a 6 foot boom, but 27 foot elements. If you can get it at least 35 feet in the air, you would be able to routinely work anywhere in the world with it. I have the TH3, and it covers all of 15 and 20 meters with an SWR less than 2:1, and all of 10 meters except about the top 50 KHz. Resonant SWR is about 1.2. I think the difference in gain between a 2 element and 3 element beam is only about 2DB

Hi Arie,

The advice comes filtered through my own experience doing the same thing you are doing now. Instead of an antenna modeler, my work is a personal web robot that does what is called "Text Data Mining." I was in D.C. last summer when the FBI showed some interest in it.

If anyone is interested in their own search engine, they can find my work-in-progress called RoBot Explorer at:
http://home.attbi.com/~r-w-clark/mine/index.htm
It consists of a single Java Bean Jar (which on newer Windows machines will open automatically, or you need to "associate" it with your copy of the Java Runtime Executor (JRE)).

Almost every installer I've encountered from a commercial purchase has an entry level non-commercial use version available - or they did when I was interested in them.

If your code was developed and runs on WinME, it is the miracle product of the millennium (WinME is an abomination - I stepped up to Win2K and won't look back).

Hi Art,

Even at DC, when speaking of resistance, a longer path is a lossier
path. The original poster is connecting to a loop. He has identified
an alternate connection to the interior of the loop element, a large
radius tube. I responded with:
>
>Secondly, attaching to the interior means the RF path will simply flow
>along the inner surface to follow your cable back outside through that
>puncture in the RF shield (how the cable got inside in the first
>place) and complete its business in the usual fashion. However, as
>the currents are huge, why would you add non-inductive length?
So, for most here, a shorter path has everything to do with RF. As
much so, or more than at DC.

I would ask you the same, slightly altered question:
>why would you add lossy non-inductive, non-radiative, non-supporting length?

The shortest surface path is the path of least r-f resistance and impedance.

Hi Chris,

This one usually throws most and they respond with conventional
answers.

However, matching with a folded element is walk in the park. There
are several analysis available for a folded antenna, and all fit
together by virtue of what is known as "superposition."

One of those analysis is done with a transformer model. In that
model, it is the ratio of the turns, or the ratio of the wire
diameters that determines feedpoint R. You scoffed at the notion of a
3 wire model, but this is a common alternative.

You need a 1:5 or a 1:6 boost. You can add wires and go from there,
or you can take two different wire gauges and let it do it through
those ratios (this may take some experimentation along with wire
separation).

> SWL, and not only hams, can understand your transmission.

I don't care if the general population can understand me. They can't
talk to me, so whats the point?

> Instead, with the increased ease with which signals are digitized,
> DSP should really be required knowledge.

I know plenty enough to be able to use DSP. I have DSP built into my
radio, and I have it outboard on my computer. Most of my PSK-SSTV,
etc, etc programs also use DSP. Big deal...

> I mean, it takes so little nowadays to feed the signal into an audio
> board

You said it... So what makes it so special?
>
> In fact, consider this: DSP should be required because, in case of
> emergency, you hook up your PC/laptop audio board to the radio, and
> there you go,
> modulating any way you want...

I can train a smart monkey to do that. But overall we have a problem..
If I have an emergency, can I call you to come over to the scene and
bring a laptop? I have a radio in my car, but no laptop yet. Of
course, I could talk into the mike, or use a code key, but I want to
be stylish like you. Hummmm, you say you live many states away? Take 5
days for the laptop to get to my accident scene via UPS? Oh well...
I've still got my hand to keep me company in the meantime...

> Code is what keeps me getting a ham licence.

Why? Are you "gifted" or something?

> I just don't suffer fools gladly, and the code requirement is foolish.
> If I want to waste time, there are many more pleasant ways to do it.

Well, ok then. A man's got to know his limitations...

>
> Oh and one more thing: I think it is incredibly funny that in a
> country where you can get a driver's licence without knowing how to
> operate a stick shift, you cannot operate ham without knowing code.

What does a country have to do with this? It's international treaty.
BTW, in this state, the car you take into the driving test will
determine if you need to know how to manual shift or not. If it has a
manual transmission and you can't shift it well enough to drive, you
won't get a license. You will have to buy a new car with an automatic,
and retake the test. Expensive way to get a drivers license if you ask
me...

>
> There, now flame me.

Naw...Just pity...Anyone that lets a snail slow 5 wpm code test stand
in their way, doesn't really want a ticket too bad. What does it take
to learn? All of two weeks? Good grief...How long did it take you to
learn all about DSP?

Next.... MK

2911. Re: 7 steps to improve ham radio.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-21 19:59:58 UTC

Oh I am quite willing to learn things in general!
But the point is, there are so many things to learn,
and I prefer to learn useful things to useless ones.
I'd rather spend time learning more about DSP, that can
be useful to me to post-process radio signals, than code,
that I am likely to never use.

And another poster commented that I simply not motivated enough
by amateur radio to learn code.
True, by definition.
I sometimes listen to what hams talk about; 95% of the time
they talk about their radio setup.
The idea of having to learn code, get a licence, and build an
antenna, to be able to talk about my radio on the air
is ... uh ... less than overwhelmingly enticing.

I predict that, with all the new technologies available now
(cellphones, internet, computers, etc etc), amateur radio will
simply die out for lack of interest; the ARRL and others are
doing a pityful job of getting the newer generations involved.
Too bad, because some things going on with packet radio,
computers, routing etc are incredibly cool.

They keep up this old-fashioned requirements, and they don't
realise that, as the younger people are turned off,
their radios will also eventually be turned off, when FCC
reclaims the frequencies.
They see the refusal of somebody to learn code as that person's
problem, and they don't realise that the lack of membership will
soon be their problem.

Sooner or later the FCC is going to reclaim those frequencies
due to lack of interest, and nobody in the US consituency will care,
except the 0.0001% of the population - hardly a political constituency.
Come on - listen to the actual _content_ of ham conversations:
if SW bandwidth ever becomes valuable, I don't think ARRL has a chance
to argue that there is something worthy going on there.
And the original purpose, to spread the knowledge of radio technology,
is moot now - with so many other important technologies, why would
one worry so much about radio?

Many hams are now in their 50s. I predict that by the time they are
dead, in about 25 years, amateur radio will also be dead, reduced to
a small number of frequencies used for emergency communication.
All the rest will be commercial bandwidth.

NOW AVAILABLE ** New Program STUMATCH.exe"

This program assists with the design of stub-line transformers used for such purposes as matching the feedpoint impedance of radio antennas to the Zo impedance of the transmission line from the transmitter. The program is applicable to both balanced-pair and coaxial lines. These and similar types of transmission line transformers have traditionally been designed with the aid of Smith Charts. The superiority of this program in respect of time, operating simplicity, accuracy and user appreciation is clearly seen.

Peter,

That's great news. You should know that you can get involved hip-deep in amateur radio, including DSP (pre- and post-process) without learning a single dit of Morse code. Just take the written exam, Element 2, and you'll be licensed to experiment on literally many GHz of really prime spectrum.

We'll be looking for you to join us soon. I'll bet you can teach us a thing or two.

Let me explain: it is an unnecessary and anachronistic barrier to entry. Frankly,
'the code' was really a prominent mode of operation at one time, but now it is
mostly a barrier to entry. It is MUCH MORE useful to center ham radio on
creative endeavors (which can also include working long distance in poor
conditions with code.) I am NOT anti-code, but I am anti-code exclusivity.

There really needs to be a basic ham license w/o code. To work at all in the
'code' bands, you'll need to pass the code test (similar to the good old reserved
bands for extra.) To be able to work anything but phone in limited bands,
you'll need the higher technical endorsements. So, there would be the
basic general ham license, which only provides limited communicator 2M,3/4M band

permissions. After that, for the real traditional 'u build it' ham stuff, then your technical endorsement would give you access to all but the code bands. There might even be multiple levels of technical endorsement (e.g. HF, UHF.) For the code bands, there would be the <10wpm bands and the >10wpm bands (or even finer grain.)

For example, more often, a ham radio operator SHOULD be able to grab a $2 PHEMT, create a simple board (with VERY FEW components) and have his/her 1dB NF 2M or 1.2GHz preamp. Nowadays, the poor schmuck will be spending $120 (or so) for some boutique preamp with 'magic parts or things' in it. (Well, 1dB NF would be a little tricky, even with a .2dB NF PHEMT, but you get my idea!!!)

Here in the US, technology is moving offshore, and even for strategic reasons, helping to motivate technology hobbies other than computer geekdom would be a VERY GOOD THING.

I'd much rather live in a world where ham operators can experiment with new or forward looking modulation schemes (sometimes with DSP), rather than only plan for a post-WWIII world, where there are a few radio sets and morse code is the only economical way to communicate.

The Morse requirement advocates seem to be approaching the fringe status of those who had stocked up their food for the YR2000 'issues'. I am NOT against Morse code, but against the prequisite for significant ham radio operation. The Ham community does have ALOT of morse operators, but TOO TOO FEW individuals who build their rigs (even significant parts of them.)

There are some cases (like you) that have the code and technology, but that isn't wrong. You would have both the code band endorsement and the experimental band endorsements!!!

John

We've got great news for you, John!

You can live in that world TODAY without studying even a single dit of Morse code! Just hustle on down to your next local VE examination session and tell them you want to take Element 2 of the exam. Within days you'll be licensed to tinker and experiment on literally GHz of prime spectrum with DSP, spread spectrum, or whatever other modulation scheme strikes your fancy. While you're at it, join AMRAD, TAPR, and AMSAT and participate in any of their dozens of digital and space-borne technology projects.

http://www.amrad.org
http://www.tapr.org
http://www.amsat.org

We're looking forward to your joining us.

HAW! That's absolutely correct! What's more, by leaving the
organization, its influence with the FCC (who is actually in charge of
making any and all of the proposed changes) is reduced.

Even the Bulgarian judges shake their heads in disgust over the poor
quality of the troll.

> Why not just drop the archaic code requirement,

FCC's hands are tied on that one. The ITU treaty requires code tests
for an HF ham license. FCC isn't going to violate the treaty - they
said so in their Report and Order. If/when the treaty changes, FCC
will most probably eliminate Element 1 - but not until then.

Meanwhile, FCC has already reduced code testing to the barest minimum
that they think meets the treaty requirement - 5 wpm. Is learning
enough Morse code to pass the current 5 wpm code test really so
difficult?

> beef up the theory
> requirements

How? What, exactly, would you change?

Many of those who commented on the recent restructuring offered
practical ways for the FCC to "beef up" the theory requirements for
the higher-class licenses. In response, FCC reduced both the number of
tests and the total number of questions for each license class.

> and get hundreds of new, excited members tomorrow?

We're getting thousands of new, excited hams each year right now. The
number of licensed hams in the USA has reached an all-time high.

> That'll be
> the biggest shot in the arm the hobby has seen in decades.

If it isn't, will you support going back to the old ways?

(I'll be reviewing the links, perhaps to bring my viewpoint up to date, and
reconsider restarting my hobby from 25yrs ago.)

Apparently, the world has changed indeed since I had my ham radio license. I
got mine (the old tech license) a few months before my First phone just to see
what FCC tests were like. I also played around, but it was before the most
interesting stuff that makes UHF on up really cool nowadays.

When I did take the tests (both the tech class and first phone) in approx 1971,
I was VERY disappointed as to the lack of technological depth (even as a
Soph highschooler) required.

In a way, we reap what we sew, and the lack of technical requirements has
further enabled a general movement towards a dominant communicator-only class
of hams. I am VERY happy to see that some of the code prerequisites have
been lifted, and I will certainly follow your links after this post. I'd also like to
see alot of very broad ham interest, that isn't dominated by communicator
type stuff, but also include more technology than currently today. Technology
MUST NOT dominate ham radio, because it is easy to overshadow the
purpose of communication. When communication almost fully dominates the
hobby, esp archaic modes, then technology might be getting too much of
a back-seat.

I'd certainly be willing to advocate a license class for ham radio operators that
would ALMOST make that endorsement into an indicator of some technical competency.
With any significant motivation of the level needed to learn code at 13wpm or

even 5wpm, the newbie ham could almost become a naiscent EE*... (*Well, maybe that is a little optimistic, but not too far off.) Perhaps I'd be more accurate to claim that a person could at least understand the terminology and the issues of design, building, testing and even computer interface. This would provide the toolset that would allow the more motivated individuals to continue on with some self-schooling.

It is probably fairly clear that my own interests are of a technical nature (both EE and software (OS, DSP).) All of my ham hobby interest was based upon the technical and innovation side, but that had seemed to be too de-emphasized.

I'll definitely give the ham stuff a look-see again. My own interest, being technical, would also include helping people who want/need to learn how the stuff really works :-). I am also NOT INTERESTED in taking anything away from ham radio -- code is good, but almost complete understanding and significant (not necessarily complete) technical self-sufficiency is also good.

John

I am VERY HAPPY and encouraged about this. I happen to see ham radio as
a potentially great hobby (and important in my past), but also a wonderful
strategic asset from both the historically too-deemphasized technical training
ground and also the operational (emergency and communications) aspects.

Wouffgang Larry, I don't see anything in there about White Supremacy
so maybe you're almost legitimate.

1. No Automatic Renewals - Agreed. We need to keep this economy
rolling one test fee at a time.
2. passing score 90% - Make it 100%. If Bruce Without Error can do
it, anyone should be able to do it. Some may have to study, though.
3. Code elements 13 wpm for General, 20 wpm for Extra. We've had 160
years to perfect the code. Lets at least get it up to the speed of a
greasy smelly dinasaur tty - 55wpm.
4. Make no-code license one year non-renewable. I've been told that
anyone can learn code in a matter of weeks. Make the NCT 6 weeks
non-renewable.
5. Cancel your league membership until they improve things - That's
been tried - just cancel it.
6. Complain to the ARRL when-ever you hear an idiot on the air, and
Complain to Al Gore when you see one on rrap (cc: Al Gore).
7. Turn in rule breakers to the FCC - Cuffed and stuffed? or just
send in their call sign?

Dick, you got a fever, man? I've not once read anything like that
from you. Not once! But I accept that as an earnest remark.

And in the "easily implemented" remark, it may be easily implemented
if you've been -trained- in the USE of Morse Code, but just learning
the code characters and passing an exam doesn't make it easily
implemented. You have to use it. And to use it you've got to have
people out there not only willing to put up with every little mistake
you make, but to actually be there and work through it. Listening to
W1AW and code tapes may make one an Extra, but it doesn't make one a
CW op. Meanwhile, 160 years after the invention of morse code,
novices are segregated to spaces and places where few are willing to
go.

> Does that mean I or any other CW supporter would in any way advocate
> use of CW -at any time- to the exclusion of better more efficient modes?
> Of course not, again despite the rumblings of some anticoders posting

Richard for some reason my Google only updates twice a day,
so there are many additions before I read my own post!
Anyway I understand that Roy said re the 'shortest' path but for
me that was just an assumption, that the shortest path was
also the best impedance match ! Is this really the case ?
Are not the impedances different inside a tube compared to the
outside? Maybe I am seeing too much in the problem.

Reg may I ask a question regarding the word "stub"
for instance I have added a similar thing to what is
known as a "stub" in the center of a dipole purely to
make a phase change the feed still being made
delta fashion. Are both being called :"stubs"
acceptable within the realms of ham radio, if not what
would be the correct description for a "stub" that is
not terminated at a feed point?

I agree with Peter. As an EE, I would pass that test right now. As I have said before, we don't demand that every computer user learn 2s complement math (or even DOS) prior to allowing them to use windows, linux, etc. The very idea sounds rediculous to us. The CW requirement is no different. Just my 2 cents.

There already is - it's called a No-Code Tech.

Let's just keep it simple. To work any band / mode below 30 mhz. you need a
higher class license (oops, that's how it is now... :>)

Add the DSP yes, take out code not.

Several times every year, shortwave conditions are poor enough that voice
transmissions are unitelligible. If you don't have a computer to work the
other digital modes, the only possibility left is CW.

There's no reason to flame anyone. It is a difference of opinion that should be calmly debated.

Didn't read up on the World Trade Center disaster support did you. All other communication services were so overloaded that it took 1/2 hour or more to get through using the conventional services. Over 300 hams gave over 5000 hours of communications support and it was indeed needed.

Actually learning all about DSP is useless as it's built into the radio and
I don't have to do anything.

There is much more variety in the conversations on CW than I've typically
heard on voice. The range of topics is amazing. I communicated with
retired teachers, "talked" about eBay, etc.

There is a basic ham license without code. It's called Technician. They
have all privileges on all ham segments above 30 megahertz. There are some
fine individuals doing great work in that realm. And some are even using
the 6m and 2m code band segments to work on their code so that they can pass
it to get on the HF bands.

Actually if you limit them to phone only until they learn higher
endorsements, too many will simply stay there. Allowing phone privileges
should be the treat that they get after proving themselves competent in
other areas of ham radio.

An amateur from San Francisco, who was in NYC that day and ended up acting as shift supervisor on amateur comms for about a week, commented at a talk he did: "You know all those pictures you saw of people running away from the disaster, talking on their cellphones? They weren't talking. They were listening to busy signals."

In a more modest (but still applicable) example: the Croy fire, in the Santa Cruz hills in California, just over two months ago. There were a lot of firefighters, forestry-service folks, Red Cross workers, etc. up in the hills, in areas where none of the conventional comm services would work reliably or at all... no cellphone coverage, fire radios out of range, etc. The amateurs from the local city and county RACES groups were still "up and operating", passing traffic both simplex and through local repeaters, when nobody else could get through.

I fully expect the same thing to happen when (not "if") the next big earthquake hits here in the San Francisco Bay area. I'm told that almost all of the local cellphone service depends on a limited number of landline trunks and coordination links which run between here and Los Banos... right across the Hayward fault. If that fault is the one which cuts loose, the landlines are gonna go down, and the individual cellphone towers will go off-line. Even if it's a different fault which shakes, the cellphone system is likely to overload and crash just as it did in New York City.

I'm equally concerned about those areas of the country which have switched their public-service radio systems over to centrally-coordinated "trunked" radios. They're convenient and flexible, but seem to me to be very vulnerable to single-point-of-failure problems. In these areas (and the SF bay area isn't yet one of them), the police and fire radio system could end up going off-line all at once if the coordination computers fail.

Amateur-radio systems have the advantage of being much less centralized than most official and commercial communications systems, and are thus somewhat less likely to be completely clobbered by any given disaster. The amateur traffic-handling capacity is not very large, but it's often robust enough to remain available when most

other systems have failed completely.

That's a big part of what spurred me to get my ticket, last spring,
after many years of procrastinating.

One of the best small beams I have used in recent years was a 2el tribander
I made from the DE and Dir of a Cusshcraft A4. I didn't have room for the
whole thing once I moved, so I came up with the 2 el based on modelling I
did...and it worked great. Maybe CC makes a 2el version.

First, an honest thanks for yet another useful program, Reg.

However, it certainly won't replace other transmission line tools I
use, because it's really not very often I care about just matching an
impedance at a single frequency. I'm interested in a wide variety of
tasks, including matching at multiple frequencies, being able to use
lumped as well as transmission line components, being able to
understand (visualize) the degree of match over a band of frequencies,
and designing pass-reject filters. I'm sometimes also interested in
the effects of line loss, generally when the impedance ratio is high.
For my work, it's not so much a "vs" as you put in your subject line,
as it is another tool to join Smith and Gates and some others, each to
be chosen when appropriate.

Cheers,
Tom

Art,
I didn't refer to any antenna literature when writing the program. The adjective 'stud' has been locked somewhere in my mind for about 58 years. I had a vague recollection it applied to short lengths of balanced-pair transmission lines, sometimes open and sometimes shorted at the end which was not connected to anything else. For the first time in my life, when writing the program, I was in the position of having to describe in words what the thing actually was. So I could do little else except assume the meaning of the word had not drifted during the last half-century or so.

I have also applied 'stub' to coax lines without giving it much consideration. lot of thought.

When I first saw your message I panicked at the thought I had somehow used the wrong word and that I should have to go back to square one, rewrite the source code, recompile the executable code, overwrite all 5 of the various backups, plus the 3 associated files in the website. I would then have to send messages to all newsgroups I had advertised in, apologising for the misery caused and asking everybody to download again. All unpaid for as usual.

I looked up the word 'stub' in my dictionary. It just gave a long list of things to which 'stub' could apply not one of which had anything to do with transmission lines.

Inspiration then flashed. I remembered somewhere around the house there was a past edition of the ARRL Antenna Book. After a few minutes search it appeared. There were 3 references in the index and several pages of where stub lines are used in transmission lines.

There was no reference to the gadget you describe as a 'stub'. I think you are at liberty to use 'stud' anywhere you like provided you make sure to define what you are talking about the first time you use it. A drawing? If it is not a transmission line but is in danger of being confused with one then change its name to something else. Call it a widget.

I think 'stub' can be applied to anything which is shorter than normal and perhaps ends abruptly. Like a smoked cigarette end. Or a stubby finger.

Reg.

Hi Richard,

I can understand the smaller radius of the inside of a tube having
less surface area and a higher
inductance than the outside. What I am wondering, is there any
benefit to leaving the end of the
tube open rather than closing (flattening) it when using it as a tank
coil. It would seem that
leaving it open would give a lower total effective resistance by
allowing rf to flow on the inside
as well as the outside. Giving the benefit of two surfaces rather than
one.

2945. Info on RX noise bridge from Ham Radio Magazine

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-22 01:44:53 UTC
From: kiddi@marel.is
Message-ID: <b7cca008.0211211744.3c1ea1c3@posting.google.com>
Source record: 130884

Some years back I constructed an RX noise bridge from an article in Ham Radio Magazine. The article appeared probably sometime in the 1980's, but possibly even back in the late 70's.

Anyway, I need the schematic for this bridge to determine exactly how the R and C are connected into the bridge, as I just came across the unit from my junk box and would like to put it to good use. Does anyone have the schematic and/or any other info that may be relevant to this construction? This specific design was a little different from most others in that it did not use a toroid transformer to generate the balanced noise signal, but instead it used some kind of a transmission line arrangement - a section of twisted wires folded up inside the unit.

It looks like I have lost this article, so any info would be appreciated.

Dave Platt wrote:
"---the police and fire radio system(s) could end up going off-line all at once if the coordination computers fail."

Few new systems are perfect. Improvements are likely to make them better. Satisfactory corrections are almost certain because area insurance rates are in part based on the independent communications capabilities of
its fire departments. Jurisdictions respond to the incentive of lowered insurance rates.

Any disaster is possible, but repetitions are less likely due to subsequent corrections.

The availability of ham radio backup is not taken into account in insurance rate determinations, as far as I know.

Reg:

Thanks for the new program.

I have been a user of stubs for matching HF wire antennas [usually open wire or window ladder line fed antennas] for years. In practice I have always "designed" them "in the air" so to speak, cutting them to length experimentally to get the match I needed and then keeping a few around with aligator clips on the ends which I often used to quickly change bands by simply clipping them across the open wire feeders at the appropriate point.

I have been wondering for a while, and I have asked Cecil about this on the NG, but didn't seem to get his interest, whether stubs might be used in an economical adjustable matching scheme similar to Cecil's adjustable length transmission line system.

In fact, some combination of Cecil's length adjusting scheme coupled with some adjustable length stubs with adjustable open or short circuit far ends might just be more economical and wide ranging than Cecil's current scheme.

Your program should enable someone [Cecil?] to study the possibilities for an adjustable stub "tuner eliminator" to compare with Cecil's famous adjustable length feeder scheme.

I would say Art said it best, Electricity ALWAYS takes the path of least resistence.

That being the case, if its a wire w/ no other components (IE resistors, caps, coils, chokes.) Then the shortest wire would in theroy have the least resistance. Mostly because in any conducting element there is loss.. So the longer the wire, the greater the loss. In standard Coaxial cable that would be roughly 3db / 100' cable. This loss is also effected be the material of your elements. (IE: gold would have a lot less loss then say aluminum) the better the conductor the less resistence and the less loss.

Then you have impedence too, (I always mess this up) but, for the same reason you use an SWR meter to match your antenna you want to balance your load to get the most output as you can. If you start to wrap you line, you create impedence. A coil blocks AC, and passes DC current. and a capasitor passes AC but blocks DC.. lol electronics 101..

I hope this helps.. I only post this to put my 2 cents in, helping if I can!

Wouff Hong,

I'm not sure where you from, but that's beside the point. I read your suggestions to improve ham radio, and, as some one who is very proud of the organization they are from you wanted to let other people know your thoughts. As we both can see, it's raised a lot of havoc and questions and that sort of thing.

I must agree with you about some your suggestions, but lets look together at what you stated.

> Step 1: No more automatic renewals. Individuals must retest and
> pass all elements required for their license class.

-I feel the same way with this, because I think everyone should retest to get their driver's license every 10 years. Now we gotte realize how much a pain in the rear this would be, and not only take people away from this great hobby. It would be a good idea instead of retake tests, but to really encourage individuals bursh up on their skills, knowledge or electronic theory, etc.
>

> Step 2: The passing score for written exams needs to be raised to 90%.

-Again I agree that the level of accomplishment should be raised so people have good moral standards and treat with repect what they have their hands on when they worked hard to earn their Amateur license. 90% in manys' opinion would be to high; and it would frighten and discourage people.

> Step 3: Code elements should be 13 wpm for General, and 20 wpm for Extra.

-Morse code, a favorite of many, and not so great of many, but who is to say good or bad. Personally, and maybe others like yourself have to say that morse code is the the "basics" or any form or radio. Just because we had to take those tests when we got our licenses doesn't mean others have to. It would be a better idea to encourage people to do the morse code because if they do, I've found they stay in radio longer because if they have what it takes to learn the morse code; they'll generally apply the same learning habbit in other areas of radio. Please don't Misunderstand me, many people don't like it and are very active. But lets encourage and not say anyone has to this or that.

> Step 4: Make the no-code license one year non-renewable.

-Sounds like a good idea, but tis better to encourage people to move on and help them along the way, then bark at 'em like their bosses do.

> Step 5: Cancel your league membership until they decide to work
> to improve things.

-If league's don't have memberships, they can't support us and improve things. Memberships provide income for our leagues to improve things. We all should encourage people to join a league of some type.

> Step 6: Complain to the ARRL when-ever you hear an idiot on the air.

-Nobody is perfect in this world except God. When people who is arrogrant operate, I find out someinfo about them and kindly correct them over the phone or in some kind of private conversation. Nobody likes to be humiliated in public or at anytime. Besure anyone who does this makes sure the other person needing correction is open to it. As the cliche' goes; " A man convinced against his will, is of the same opinion still."

> Step 7: Turn in rule breakers to the FCC.

-Same as above; Nobody is perfect. Constant offenders have some challange with some one or something which some one needs to find out what the deal is and help him out with it. People just doing harm out of no reason does need to be turned in however.

Hope this helps. As you can see I mentioned the word encouraged lot because many people are guilty of this, myself included. When people are guided to the direction they want to go, they will go. There is a story that goes something like this. "The sun and the wind cloud were having a contest to see who could have a man in the park below take off his coat. So the wind cloud says he'll go first and the sun hides behind him. The wind cloud blows and blows but the man in the park just holds on to his coat tighter and tighter. The wind cloud gives up and the sun comes out and just shines his warm rays down below to the man. The man removes his coat and goes pleasantly about his business." If the moral hasn't bern figured out by an intillgent individual like yourself, it is that when someone is forced to do something, they simply won't, or they'll possibly grudingly do it. Ask and encourage someone to do something and they'll give it all they got for their best effort.

Hope this Helps,

Respectfully,
~Benjamin, KB9LFZ

Art, KB9MZ wrote:
"Are not the impedances different inside a tube compared with the outside?"

Art may be referring to the inside and outside of a shielded loop which the original poster asked about. The original poster asked about tarnish on the loop affecting loss as skin effect concentrates current on the surface of a conductor carrying r-f.

I didn`t express an opinion on that, but my experience with tarnished waveguide was that effect of tarnish was unmeasurable. Other posters have noted effects of tarnish on loss in cavities.

The impedance inside a shielded loop is likely different from that outside. I think it has to do with L/C.

The original questioner also said:
"---as the signal skins to the outside."

This indicates an understanding that r-f current remains near the surface of a conductor and usually cannot penetrate the conductor.

Roy said the "shortest path". I took that to mean a current path say from a point on the inside of a cavity where a coupling loop is attached, back through the hole the coupling loop uses to access the cavity, to the point on the outside of the cavity where a feedline attaches. Current follows the surface all the way. It cannot penetrate the wall of the cavity, except through a hole in the wall.

Impedance of a coupling loop, as Art knows as well as almost anyone, depends on loop configuration and placement.

Best regards, Richard Harrison, KB5WZI

2955. Re: skin effect

Newsgroup: rec.radio.amateur.antenna

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <utr8omn87hvp27@corp.supernews.com>
Source record: 130893

The impedance of the path along the inside of the tube is very high --
it's essentially a waveguide far below cutoff, and there's no charge
distribution possible that will support the fields required for
propagation along the inside. This changes if you put a concentric
conductor inside the tube, since that combination will support a field
distribution (TEM) that will propagate with relatively low loss. It's
basically why we use coax rather than waveguide at HF.

So the answer is that it really makes no difference whether you smash
the ends or not -- no significant amount of current will flow on the
inside of the tube in either case.

This all assumes that the wall thickness is at least several skin depths.

Roy Lewallen, W7EL

Hi Peter, I had just such a system installed in AZ. Stubs are probably
a good way to go when the SWR is too low or too high for my present matching
scheme. For instance, if my 450 ohm SWR is lower than 4.5:1, there's no way I
can achieve a 50 ohm SWR less than 2:1 simply by varying the length of my
ladder-line. Same is true for 450 ohm SWRs higher than 18:1. Fortunately,
I chose my dipole length so my 450 ohm SWR is always between 7:1 and 15:1.
Of course, you realize that stubs depend on reflections for their operation. :-)

I would have thought Rich would have known about how cellphones are one
of the first communication assets to be overloaded and thus become
virtually useless when something big happens.
They are trunked, and designed to handle at max only a fairly small
percentage of their total number of subscribers. Thus when something big
happens and everyone tries to call home at the same time.....

My speculation matches Gary`s if he implies open ends might lower r-f resistance and loss slightly. I havent tried it, so I don`t really know.

In my experience are 100 KW shortwave broadcast transmitters with silver-plated tank circuits. These essentially had the open ended tubing that Gary mentioned. They had this to convey distilled cooling water to the plates of the final amplifier tubes. Water connections to the tank circuit tubing were made with Saran tubing for flexibility. So, the r-f could loop around the ends of the coil tubes, I suppose, for whatever lowering of the tank circuit resistance this might contribute. I doubt that this was much help. The silver plated tubing was so large, it really didn`t need a lot of help, and it was water-cooled anyway.

Hi Richard,

It would be interesting to see the math, but the intuition suggests
that the impedance (relative to what?) would be quite high.

And it is difficult to search for an L/C solution where the lead into
the tube negates its own inductance, and that of the "shortest path"
back to the hole the lead came in.

Yep. Conversations with users reveal those systems are vulnerable far
beyond normal
point to point and base to mobile radio systems. When trunked works it
is great and as you say, very flexible. When the system goes offline
(it's all computer controlled) you're out of business for the duration
of the outage. It ALL quits. Actually this factor would seem to enhance
the value of ham radio communications in emergencies.

>
> Amateur-radio systems have the advantage of being much less

> given disaster.

Exactly. Hams are pretty well distributed throughout the population and
incidents which might cause a serious problem to centralized systems
have much less effects on ham radio's capabilities.

The amateur traffic-handling capacity is not very
> large,

As a longtime emergency communicator I can state with some experience
that throughput is about the last consideration when the desperate need
is for *any* communications. Limited traffic handling capability can be
VERY useful, even critical.

but it's often robust enough to remain available when most
> other systems have failed completely.

Yes, and that fact alone makes ham radio a valuable asset.

Roy, W7EL wrote:
"---it`s essentially a waveguide below cutoff---."

Roy hit the nail on the head. A tube must be at least 1/2-wavelength in diameter to propagate a wave through. Attenuation below cutoff frequency is very severe.

Radio chassis have been deliberately built as "waveguides below cutoff" to prevent r-f feedback from output to input. Waveguides are circular, rectangular. and oval in cross section. The larger dimension must be at least 1/2-wave.

Best regards, Richard Harrison, KB5WZI

Amen to the Larsen 5/8 wave. I've been using the same one since 1989/1990.
It is like the old Timex commercial, "Takes a licking, keeps on ticking".
I've whacked low-hanging tree branches, garage door frames, etc. The only
damage is the corona tip (or is it eye protector tip) came off when whacked
on a tree branch a number of years ago. Oh yeah...it works very well too!

I agree, as the politics within ham radio will kill ham radio long before
other issues will.

Step 1: No more automatic renewals. Individuals must retest and
pass all elements required for their license class.

This one I actually agree with. If the statements made by certain indivuals about "growing" with the hobby and climbing the ladder of licensure are to be true, then hams should not have a problem taking a test that should be a breeze since they have "obviously" advanced within 10 years....

Step 2: The passing score for written exams needs to be raised to 90%.

Dunno about 90%, but think that 80% sounds fairly reasonable. Add more questions to the test, and choose other formats of testing other than multiple-guess too.

Step 3: Code elements should be 13 wpm for General, and 20 wpm for Extra.

See not a huge problem there, but never understood why 13 for the General. Why not 12, or 14, or ??? What is so special about the 13 wpm? Anyone know why they chose 13 for the "middle" code test?

Step 4: Make the no-code license one year non-renewable.

2 years seems like a fairer option.

Step 5: Cancel your league membership until they decide to work
to improve things.

Hmmm.... could start a whole new newsgroup on this one.........

Step 6: Complain to the ARRL when-ever you hear an idiot on the air.

They are not our governing body, nor will I ever accept them as our "governing body." It is bad enough that they have taken over the testing duties.

Step 7: Turn in rule breakers to the FCC.

DUUUHHHHH!! All should do that.... but follow proper policy/procedure when doing so. Also work towards the goal of getting the FCC to actually do something about that in the first place.

All in all, the problems people want to bitch about regarding ham radio stems back to the FCC each and every time. They make the rules/policy/procedures and they are the ones to blame. HOLD THE FCC responsible.

Actually, they should probably limit the power for the 'communicators' to less than 100W, and the higher technical licenses would allow for higher power :-). The 30MHz, I guess, is still a treaty thing, and indicative of stagnation. Maybe the 'communicators' with little technical criteria might even be limited to 10-50W at VHF and above.

The goal isn't to punish people, but to motivate people to learn how their stuff works. I suspect that the VHF bands are too full for much experimentation, but the technology for homebrew on 2GHz on up is now relatively achievable by mere mortals.

Wouldn't it be cool if people really designed/built their own stuff that makes sense to do so, rather than buying their devices from boutiques? Alot of stuff isn't really practical to build (e.g. the communicator 2M units, or walkie talkes), and the stuff that is extremely practical to build (10M transmitter) even with few mechanical skills, would be constrained by the code requirement.

So, for the newbie, where homebrew is more practical below 100MHz, the code constraints tend to continue their burden.

John

I look at the code requirement a little different..... If it is so important, then ALL radio services should have to pass at least the same minimum 5wpm as we do.

Hmmmm.... most US states already do that somewhere between every 2-4 years.... As well as they should too... And they also need to start testing senior citizens more often too..... (not gonna state what age they should start that at though...) I have worked a variety of accident scenes where the scene was clearly marked and using on the fire trucks to block the lane, with lights operational, pile-on orange cones, road flares etc, and a senior citizen still plowed into the firetruck. He claimed they could not see it..... Jeesh, you could see the scene from a freaking mile away!!!!!! Yeah, I am all for retesting on a fair basis.

> other areas of ham radio.
>
The limitations for those without the 'technical competence' endorsement should
probably be a reasonably low power like 20-50W on VHF/UHF and/or 100W for HF.
Phone should probably be the first mode of communication, mostly because
of the relative usefulness (e.g. during normal disasters, to help with communications,
phone will more often be useful rather than code (unless there is a WWIII)). During
urban disasters, if we are having to deal with code, the situation is probably
severe enough that ham communications ettiquete would be the least of our worries.

There certainly should be reserved areas of the HF bands for code, and those
people with/without code who haven't passed the technical criteria for the
technology endorsement, will be limited in power. Really, if someone cannot
quickly whip up a preamp/active impedance match for an HF frontend that
has to work in an area near a 50kW MW transmitter without overwhelming
intermod, then it kind of worries me about how the ham is going to competently
deal with the numerous issues of using their 500W-1kW rig. It isn't just
a matter of getting on the air, but also avoiding interference with TV (including
nowadays 8VSB), AM/FM radio, and other more important services.

People do get 'on the air', and usually do the right thing, but it is VERY SAD
that too few people build their own equipment. Of course, CBers had historically
been known to simply slap on an illegal 'linear', and their rigs sometimes worked
okay also (often with anti-social interference :-)).

Of course, my attitudes about technological competency can be mapped to
the equivalent attitudes of those who have already passed the advanced
code tests. In the normal profile of natural/terror disaster, the availability of
a radiotelephone communications mechanism would be much more useful
than if the 'HRO' only had a code rig.

John

Yep... overall the hobby is declining, but it is not from the testing procedures. Anything viewed worthwile by someone is worth pursuing as well as whatever obstacles along the way. The root of the problem is in the PR side. I still run into tons of people that didn't even know ham radio existed. A much smaller group associates it with CB from my own local area experiences. We need to promote the hobby more. We need to get ham radio into the schools, associate it with the cirriculums. We need to start doing things that WILL get people coming to us, to become hams. Testing sessions with a mere few testee's definitely reflects that there is a problem with promotion of the hobby. But that would take actual action by people and god forbid that eh????

I do, and so do a lot of hams that have any working electronics knowledge,
but you don't get that by simply memorizing the answers to 30 multiple
choice questions...

> Alot of stuff isn't really
> practical to build (e.g. the communicator 2M units, or walkie talkes)

My first 2 meter rig was a kit (Heathkit), as were the first pair of walkie
talkies I ever owned (Allied Radio).

>, and the stuff
> that is extremely practical to build (10M transmitter) even with few
mechanical
> skills, would be constrained by the code requirement.

The only practical 10 meter transmitter that one with limited skills
might be able to put together would be a CW transmitter, so it would be
of no use to a person that did not know code.

> So, for the newbie, where homebrew is more practical below 100MHz, the

> constraints tend to continue their burden.

What burden? There is nobody forcing them to become a ham. It is something
that one does because they want to do it. And according to their level of
effort and dedication to the hobby, they are rewarded with additional
operating privileges.

I love my PW-1 amp - when coupled with an Icom rig you get auto band-change, auto-tune, and 2 in/4 out antenna selections. For DX chasing and rapid band change it's great.

But, it is NOT quiet. There are four fans in the PW-1, and each kicks in at different times (power on, transmit mode, high temp, tuner in use). The good news is that with the remote head you can move the amp away from your operating position - even put it behind a wall, because all operations are performed from the control head. So, it's noisy but you can put the noise somewhere else. Otherwise, if the amp were right there on my operating desk I would be an unhappy camper! ;-(

Actually, the licenses say "Technician". Nothing about code or nocode
on any FCC ham license. And all US hams are allowed to use Morse code,
test or no test.

A distinction needs to be made between those who are against the code
TEST, and those who are against code USE.

> > > To work at all in the
> > > 'code' bands, you'll need to pass the code test (similar to the good old
> reserved
> > > bands for extra

WHY? There's no requirement to pass such a test today. In fact, 6 and
2 meters have the only "Morse only" segments - and they are open to
use by Techs who haven't passed a code test.

Probably a good idea, because then the RF exposure questions on the
entry-level tests could be tailored to the power levels permitted.

> The 30MHz, I guess,
> is still a treaty thing, and indicative of stagnation.

Nope. It's simply a treaty requirement. Once upon a time the
requirement was for all ham licenses. Over the years an exception has
been included for VHF/UHF because there is relatively little routine
use of Morse by hams on VHF/UHF. The limit has gradually been lowered
at various WRC conferences - 1000 MHz, 144 MHz, 30 MHz. Next year it
will probably go to 0 Hz ;-)

Before judging whether "code is dead" or "obsolete/outdated/nobody
uses it anymore", try actually LISTENING to the ham bands below 30 MHz
- particularly the lower ends of the bands, where Morse use is most
common.

This weekend would be a good time to listen.

> Maybe the 'communicators' with
> little technical criteria might even be limited to 10-50W at VHF and above.

Sure.
>
> The goal isn't to punish people, but to motivate people to learn how their stuff works. I

Plenty of room on all bands for experimentation.
>
> Wouldn't it be cool if people really designed/built their own stuff that

I do that, and have been doing so, for more thna 35 years.

> A lot of stuff isn't really
> practical to build (e.g. the communicator 2M units, or walkie talkes), and the stuff

>
> So, for the newbie, where homebrew is more practical below 100MHz, the code
> constraints tend to continue their burden.

How does the requirement to learn code at 5 wpm just well enough to
pass a test unreasonably constrain the ability to build radio
equipment? Hams have been building rigs long before there were
licenses without code tests. Heck, I built my first transmitter at age
13 - right after I passed the code test. That was not at all unusual
in 1967.

The REAL "burdens" of home design and construction today are the
practical and economic constraints. Manufactured ham gear, and kits,
are inexpensive and plentiful today. What sort of projects would you
recommend for the raw newbie?
Do you think it's practical for a new ham without an extensive
electronics background to design and build an HF SSB transceiver as a
first project?

2978. 4NEC2 ver 5.0 Questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-22 13:57:59 UTC
From: jim.bolinger@lintek.aeroflex.com
Message-ID: <8d5ec8a2.0211220557.5c68dad2@posting.google.com>
Source record: 130912

I have it installed on a Windows XP system (the 4nec2X version)

It seems to run ok. At least the GUI part, as I can load and view antenna geometry. However, when I do a 'Generate' I do not see any 'out' file. The DOS window comes and goes so fast that I suspect there is some error that it is bombing out on, but it is too fast to read.

I noticed the INI file has some explicit directories defined. Should these be changed to reflect how my system is set up? I have 4nec2X installed in c:\Antennas\NEC\, not directly at the root.

There aren't any hardcoded directories in the program, are there?

By the way, I am very impressed with the part that I do have running. Well done, Arie!

James,

thanks you for your nice words and especially for your comments.

I must agree with both your two(three) complaints. I also noticed
these.
The 'file-name' display length has low priority on my 'to do' list.
The entry system is more important but this requires a substantional
amount of (re)work. For now I am busy including a Genetic Algorithm
based optimizer, but this might be the next project to start.

Anybody having suggestions about how to graphically edit or input XYZ
coordinates for 3D structures ? (for instance, how this is done in
commercial 3D cad software ?)

Arie.

Dee, N8UZE wrote:
"Didn`t read up on the World Trade Center disaster support did you."

I appreciate whatever ham radio did to alleviate 9-11-1.

I expect most ham messages were of the "Aunt Tessie says she`s OK" variety. The authorities likely wouldn`t allow hams entry to the scene.

People paid to make public service communications work pretend to seek ham support, but the support they seek is only for their budget increases. Forces external to their departments are threats to their control and expenditures.

As a disaster service, amateur radio has forever lost clout because of cell phones and plenty of well equipped media.

Cell phone toters outnumber ham radio toters 1000 to 1. The 911 call therefore is that much more likely to come from a cell phone.

In my area, public authorities have elaborate mobile communications centers ready to roll to any disaster, even for loan out of state. Here, they also have dispersed communications centers ready to contact the mobile centers. Hired personnel are ready to expertly handle communications and perform under threat of job loss or hope of commendation and salery increase.

Match that with ham radio!

Best regards, Richard Harrison, KB5WZI

What would you rather have, all hail Al Gore ?? Given the choice and the circumstances, I would rather have 'ol Georgy-boy in there than what we have had for the last eight years. At least now we are trying to clean up the situation instead of sitting around telling each other how great other cultures are and how bad America is.

I am no fan of the present administration in some areas (i.e. the Patriot Act), but I will take it over the alternative. I would shudder to think what would be happening if Al Gore had gotten in there. You could pretty much just hand over you guns after 9/11.

Gentlemen it seems that you all have a great understanding of 'stubs'
and what they can do. Why is it that you cannot consider a parallel
circuit in the same
light? With your knoweledge and understanding it should be very easy
for you
to look at a parallel circuit(or loop if you wish to call it that)and
compare its function to that of a 'stub' circuit that generates
'profitable' radiation.
I for one would benefit greatly for your inputs on such a comparison
if you could give it the time.
Best Regards

2988. Grounding chimney mount antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-22 15:40:00 UTC
From: H Johnson <classy-hjohnson@daystardev.dyndns.org>
Message-ID: <fbjstu8uhkoubcsasdeaf4htrcc7poi3i5@4ax.com>
Source record: 130820

I am considering placing my antenna (ham and scanner) on a mast
mounted to my chimney and driving a ground rod down close to where the
coax will be entering the eave.

For grounding, do I need to ground all the coax braid feed lines
(eventually there will be three feed lines) to the ground rod? This
would create a "U" shaped cable path outside the house since the coax
would have to go down to the ground then back up into the eave.

Or is running a solid copper ground wire from the mast to the ground
sufficient? Or do I need to do all the above.

Any suggestions/experience would be greatly appreciated.

- H. Johnson

Try instead the excel spreadsheet MultiNEC of Dan, AC6LA

http://www.qsl.net/ac6la/index.html

This contains a NEC engine and read many different formats (AO; MMANA;
Antenna Model, EZNEC,NEC) and save them in NEC or EZNEC format
Use the usual spreadsheet to plug in the numbers in X;Y;Z plane and watch
the result in 4nec2

> "---as the signal skins to the outside."
>

>
> Best regards, Richard Harrison, KB5WZI

Richard I believe the term 'skin effect' is being somewhat misused
and it could be by me ! Radiation will not occur because of the flow
of
current alone even tho the electrons do accelerate and deccellerate.
For radiation to occur there must be no space constraint and thus that
is why
we talk of "skin effect", but it must always refer to an OUTSIDE skin
and not just a "skin" which can also refer to a INNER surface where
radiation is constrained such as with a coax. If one uses a tube that
has a thickness
of the so called 'skin depth' for a given frequency the remaining
energy will not
move to the inner skin surface to radiate but will continue to
"struggle' to the outer surface where it has the freedom to radiate.If
a additional conductor is placed within this tube it will only see a
single resistance value which does not include a RADIATION resistance
which like a coax will thus conserve energy.
Remember I have no formal training in radio stuff and that may well
lead to erronius thinking on my part (probably have used different
terms to the norm also)
Note 'Out of the box' thinking provides radiation

"W6DKN" <w6dkn-nospam-@qsl.net> wrote

: And according to their level of effort and dedication to the hobby,
: they are rewarded with additional operating privileges.

Nope, has nothing to do with "effort and dedication".

Hang around here long enough, and you will see someone write
something like:

" A really tough written test would surely separate those
who really have an interest in the hobby.", or..

" Other, more relevant, methods can establish an applicant's
dedication to the service.", or..

" I think it is effective at minimizing the undesirables.",
or..

" ..... the key to maintaining the quality of hamming is
making it something to work for.", or..
.
"My opinion is that any obstacle you put in the way to any
achievement guarantees that only those with dedication and
strong interest will get there."

All of the above quotations, gathered from recent threads, were
made by serious and well-intentioned licensees who want the best
for the Amateur Radio Service.

All of the above quotations also completely miss the mark, in
that they suggest that the examination process is the key to
ensuring that "the right kind of people" (those who are
"worthy") become licensed and, by extension, that "the wrong
kind of people" get filtered out.

First, the testing procedure is an "entrance" exam, not a
"graduation" exam.

Second, while "interest", "dedication", and "hard work" might
be hallmarks of good amateurs, the FCC and ITU regulations

do not specify levels of interest, dedication, hard work or other measures of "worthiness" as requisites for a license. Therefore it is not the function of the examination process to determine (even if it could) if an applicant is "worthy" but rather to determine if he/she is QUALIFIED to use the spectrum assigned. There should be no "dumbing down", but neither can there be a requirement that the examination process screens out applicants who lack "commitment".

Don't get me wrong here, folks. I believe that the examination process ought to be rigorous enough to determine proper knowledge and skills so that a new licensee does not inadvertently trash the bands, hurt themselves, or harm other users/uses of the spectrum. I am not even suggesting that Morse testing is a "good thing" or a "poor idea". But I have no expectation that ANY examination can filter out "unworthy" applicants who lack the proper dedication or motivation.

Even if it could, who then would become the arbiter of "worthy"?

Art, KB9MZ wrote:
"If one uses a tube that has a thickness of the so called "skin depth", for a given frequency the remaining energy will not move to the inner skin surface to radiate but will continue to "struggle" to the outer surface where it has the freedom to radiate."

A thick conductive tube prohibits r-f current invasion to any significant depth. R-F can`t penetrate such a tube. Coax and waveguide don`t leak r-f if they are any good.

If such a tube has a wire running through it, radiation is shielded between the wire and outside world.

Current flow inside the pipe on the outer surface of the wire and the pipe`s inner surface operates as a transmission line. Current is restrained by Zo which ideally is the sq. rt. of L/C.

Without a wire through the pipe, the pipe will accommodate and propagate only wavelengths smaller than a dimension of 1/2-wave for the largest size of the pipe.

In any case, not much radiation escapes a good feedline accidentally.

A radiator has both radiation and loss resistances which remove energy.

To clarify doublet matching, I suggest the ARRL Antenna Book, edition 19, page 18-5.

To clarify skin effect, I suggest the 1955 edition of Terman, page 21.

To clarify transmission lines, I suggest page 82 of the 1955 Terman opus.

To clarify matching with single and multiple stubs, I suggest page 108 of the 1955 Terman opus.

Best regards, Richard Harrison, KB5WZI

I would suggest you consider looking at the 'half wave'
type verticals such as the Cushcraft R5 or R7 -- some of
them are showing up at the flea markets or estate sales
for a decent price. I picked up an R7 a few years ago and
I'm really pleased with it.

2997. Half-sloper connection

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-22 18:11:46 UTC
From: Bill Ogden <ogden@us.ibm.com>
Message-ID: <3DDE7362.4C21FF9D@us.ibm.com>
Source record: 130828

I want to attach half-slopers to my TX-455 crank-up tower. The tower will hold (when I finally get it installed) a 5-band quad on a mast that extends 6' above the tower top. This is not much "counterpoise mass" at the top.

I can connect the half-sloper to the top of the tower (55' level) or to the top of the middle section (37' level). Which is better? I am concerned about the need for "counterpoise" above the attachment point and also about any side effects on the quad. (Would a 10' whip above the quad help anything?)

I will have a number of radials connected to the base of the tower. I want to use half-slopers on 40 and 80/75 meters -- and maybe on 160 and 30 if I can get a reasonable match on these bands. Coax feed for the half-slopers (and the quad) is outside the tower, using the coax stand-off arms.

Thanks,

Bill

Besides, it's the Advanced and extras that cause the majority of deliberate rules violations. A tech or General might mess up, but an extra knows better and does it anyway. And how much effort should you have to put into a hobby?? Do the CW worshippers and "I hadto take a REAL test" guys have a life other than radio and are they still working? A lot of them are retired, sick and seem like they resent any changes because a new ham might not have to "go through what they did". I'm not married, but I have a full time job, other hobbies and interests, friends, pets, etc. How much of those do I have to ignore/abandon to be "worthy" to them?

A lot of people get turned off just by listening to some of the nonsense that goes on the air, and some get turned off after they get a no code ticket, and are ignored, trashed, ridiculed, talked over, etc by older hams, almost always of 20+ years experience, and almost always they seem to be Extras. If anyone should have their "plug pulled", it should be these guys. They have no excuses. The most local incident I can remember was when several hams in Detroit purposely interfered with anyone who tried to use the repeater having a call issued after the NO code was introed. This went on for some time, then they must have gotten some kind of warning, since it just suddenly stopped. AS a victim of these guys, I think something more should have been done. Andyes, I did make a complaint, complete with tapes of their nonsense.

BDK, no more CW for me, finally, it's over..

A stub generates no radiation at all. Profitable or otherwise. All the stub does is match the antenna feed impedance to the impedance of the feedline. I guess the single turn loop and cap used to match base fed 1/2 waves "ringo" could be an example of using a loop as a matching componant. But again all you are doing is matching the feedpoint impedance to the feedline impedance. As far as lines used for phasing purposes, I don't really consider them stubs myself. To me, a stub is a line that has no connection on one end. Shorted or unshorted doesn't matter. A section used in series with connections at both ends, I consider a transformer. A line used for phasing purposes, I'm not sure what to call. I usually just call them phasing lines. MK

Here's a novel idea. Let's have Extra band segments, Newbie band
segments, no-code band segments, code-only band segments and a
Dont-even-bother-with-getting-a-license segment.

Oh wait...we already have that.

Hi Peter,

You might want to pick up a reference on radar and waveguides, but one
focused at the lab bench rather than in the air. At the bench there
are a number of gizmos to aid in matching and one of the most common
is the Double Stub Tuner.

This model is an evolution from the single stub tuner that you
describe having experience with. There, with the single stub, you
were limited to maintain a relationship between the length of the
stub, and its distance from the mismatch. I am sure that you probably
placed the stub at the feedpoint, but this is the least common method
you would find at the bench. However, there is no purpose in pursuing
the minutia of single stubs when Double Stub Tuners are more flexible.
Cecil's method, in some way, mimics the Double Stub Tuner through his
combination of varying line length and the application of a lumped
impedance along the line.

Double Stub Tuners have a greater range of matching and are fixtures
in the feedline rather than moveable when using a single stub. The
art of tuning Double Stubs (on both sides of item under test, an
attenuator say) is slow and precise like a japanese tea ceremony.

The only way this could happen to a no code tech is on a repeater (unless
he is operating out of class on another band - and then he *should* be
ignored or otherwise enticed to cease transmitting).

But basing you opinions on a very limited segment of the hobby (repeaters)
is very misleading. Repeaters (especially in larger metro areas) are often
abused by all license classes, and many "old timers" think of them as
something akin to licensed CB anyway. Try working simplex or SSB instead,
you'll find a very different group of hams.

Hi Anad,

So few papers? Sounds like there's room enough for you to wade right
in and start writing your own.

You might start right now in telling us why you think it is an
interesting topic. You could then summarize the results of your
reading. And then you could offer an analysis. [and if you respect
our opinion, you show it with these gestures]

Three sentences, paragraphs, pages, chapters or volumes are merely
refrains of the same tune. Give us the hardest part of this harmony:
three sentences.

You're incorrect, Richard.

Amateurs _were_ on the scene, supporting the rescue and relief effort very extensively. Amateurs rode with the ERVs ("emergency response vehicles") out to the actual damage sites, staffed an extensive emergency-communications center, went out to the various shelters set up in churches and schools, and worked closely with the official fire and rescue services and with the Red Cross.

Dig around on the Web for the articles written by Bart Lee KV6LEE. He was there.

>In my area, public authorities have elaborate mobile communications
>centers ready to roll to any disaster, even for loan out of state. Here,
>they also have dispersed communications centers ready to contact the

In my area (specifically, Mountain View CA), the city's emergency services coordinator works actively to recruit amateur-radio assistance. City residents who have gone through the city-funded 8-week CERT training program are encouraged to work with local amateurs and to get amateur licenses themselves. There are several dozen of us who have gone through the background checks, fingerprinting, and swearing-in process to become DSWs (Disaster Service Workers) registered with both the city and with Santa Clara County.

Here in the Silicon Valley, a large percentage of the employees of any given city don't live _in_ the city - they live miles away where the housing is at least slightly affordable. I was told that precisely _one_ Mountain View firefighter lives in Mountain View - the rest commute from up to 30 miles away. In the case of a real disaster, the city's public service departments are likely to be severely understaffed for the first few days - hence, the city's strong

interest in having its residents available to provide first-level disaster support (via CERT training and neighborhood groups) and communications (via amateur radio).

In the CERT training I just completed, the firefighters and police and emergency-services staff kept reiterating: "In the case of a real disaster, figure that you and your neighbors are going to be on your own for the first three days."

Hi Bill,

The significance of this counterpoise/mass you speak of is lost on me.

Otherwise, your half-sloper's application at 80 and 160 is complicated
by the proximity of the quad (perhaps that mass you speak of). As
life is a complex web already, this proximity is benign in comparison.
Yes it will distort your pattern and disturb the tune of its match -
but not so much that any one but you is going to notice it.

37' or 55'? 55'! [but the sloper may disturb the quad]
10' whip? why not? Can you make it 21'?

3007. EZNEC 3.0 Above Ground Vertical Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-22 20:19:06 UTC
From: Mike <"scifiguy at starband dot net">
Message-ID: <3j3ttu0vqmf2kdapt1knp7qcvi05j3qf85@4ax.com>
Source record: 130839

I recently started playing with EZNEC, and ran into a problem that
should be easily solved, but I can't figure it out.

When I take a 1/4 wave vertical over "real ground", with the lower end
of the wire at the origin (in "ground", according to the wires list).,
and raise it just a tiny fraction of a meter, it goes from nearly zero
reactance to several thousand ohms. I assume that by raising the wire
the source looses its grounding, so I tried creating a second (very
small) wire with one end at the origin (in ground), and a transmission
line between the top of that wire and the radiator. This gave the
same high reactance.

Can someone tell me what I'm doing wrong?

Thanks.

In this day and age, requiring folks to do code is
pure bullshit. Do we ask computer science majors to
write code in assembly language or know DOS?

HELL NO!

Unfortunately, the ham radio community is so far behind
the times that these guys don't even know what day it is.

Give your favorite ham radio operator a dixie cup and
string, b/c that's where he or she is from a technological
point of view.

The ham radio community will continue to shrink unless
it gets its collective heads out of its asses.

Hey guys, it is 2002

You want a #6 wire from the mast to ground with as little turns as possible. As far as grounding the feedlines at the entrance, I'm kind of mixed on this. If you don't use suppressors, grounding the lines in itself is not likely to save your gear from a strike to the antenna. It probably would reduce the energy to a lower level, but I would think it will still fry the radios unless you use suppressors. I would consider that optional, and really up to you. If you intend to leave the radios hooked up, I would probably think about grounding the lines. If you unhook and throw outside in bad wx, I probably wouldn't bother. If you do leave them hooked up all the time, I would strongly suggest a ground bulkhead at the entrance with all lines grounded with gas tube suppressors. There is lots of lightning info if you do a google search. Also check the polyphaser web site. MK

Peter, all of this is getting very close to what I have been
trying to explain for many years and I have also tried to get
Cecil's attention to lure him away from his matching design.
If one looks at a closed end stub on an antenna it is exactly the same
circuit as a loop where the severed radiator gap provides a
capacitance.
If you look at a extended Zepp there are two main radiation curves,
Between these two curves the dipole portion and the stub is purely
for balancing to make a impedance match. If this space was replaced
by the capacitive loaded loop form of stub it will provide the same
varying impedance matching function by varying the capacitor.
In addition to replacing the varying stub length aproach taken by
Cecil it will also provide additional horizontal radiation that is
useful rather than 'wasting' it on vertical polarisation and non
additive radiation.
Cecil, what does one have to do to get you and others to unlock the
old
shackles and think anew?

Mike,

I am having like problems with EZNEC-3 and verticals. Unlike the old version, there seems no way to tell it to connect the source to the end of the wire. You can tell it 0% from end, but it does not put it there. Even when I think I got it right, it tells me the impedance at resonance is around 20 ohms. Maybe Roy will read this....

Virtually any parallel stub used on a single frequency can be replaced
with its equivalent parallel 'L' or 'C'. The thing that makes stubs easy
to understand is that they don't radiate (much). However, I assume your
loop does indeed radiate which makes it much more difficult to analyze
than a simple stub. The easiest way I know to predict the performance of
a leaky loop stub is to model it.

Source record: 130848

I found another strange thing happening with regard to segmentation.

If I take vert1.ez, raise the radiator 0.5 meters, and attach a transmission line to a short wire connected to ground, the impedance the program calculates at 7MHz is 0.381-j299.4. If I let it do a conservative autosegment, it changes from 10 segments to 5, and produces an impedance of 0.4535-j196. If I change the segmentation to 50, it produces 0.1183-j518.8. None of these arrangements produce a guideline check warning.

I would have thought that more segmentation would result in a more accurate model, but this looks wrong at any segmentation setting.

By the way, eliminating the transmission line to ground wire gives very high capacitance. Again, I assume this is because I've disconnected the ground from the low side of the source.

Please help.

A DC current produces no radiation for the reason you cite. However, when the current is alternating, the electrons are sho' 'nuff accellerating, and do produce a field. (Current is simply the rate of change of charge, so the rate of change of the current is the charge accelleration.) The field can be confined, as inside a coaxial transmission line or metal box, in which case radiation doesn't make it outside the line or box. But the presence of alternating current on a conductor does guarantee radiation.

3024. Re: EZNEC 3.0 Above Ground Vertical Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-22 22:30:22 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uttc6esk9dlc17@corp.supernews.com>
Source record: 130857

Connecting a transmission line to a short wire is like leaving it open circuited, even if one end of the short wire is connected to ground or something else. This is because the transmission line model doesn't allow common mode currents. So any current flowing out of one end of the short wire would have to be accompanied by an equal and opposite current flowing into the other end. One end is open, so no current flows either direction.

Increasing the number of segments doesn't always improve accuracy. A condition where it doesn't is when wires of dissimilar diameter are connected. Accuracy is best in that case if the segment lengths near the connections are as long as possible. Another is when the segment length is too short compared to the wire diameter. In most other cases, though, more segments will give better results. It's not clear just what you're measuring, and how you're determining which result is the most accurate.

You mention high capacitance. Where? If you've left the source at the end of the wire after you raised the vertical, that's what you should expect. If you have an antenna analyzer, connect the center to a quarter wavelength piece of wire (at HF, where the analyzer is electrically small) and leave the ground side open. Then raise it up a meter or so, to reduce its capacitance to ground. You'll get a similar reading.

I'm seeing that people are relying too much on the guideline checks, expecting a clean report to mean that nothing could possibly be wrong with the model. It doesn't. In the EZNEC manual, look in the index under "Guideline Check", and read that section to see just what this feature does.

Hi Roy,

I appreciate you taking the time to respond to my post. I figured someone else might have run across a similar problem, so I should ask here, rather than send you an email.

I looked at the help where you indicated, but it just says to use MININEC ground, which I'm already doing. Unless I am misunderstanding the help file, ground is as it should be.

I attached the .ez file, in case you'd be willing to look at it. I understand you don't have time to check everyone's problems, but I'd really appreciate you taking a look.

Thanks.

==========

Rich, wrong again!

You really must desist from disseminating mis-information and stick to your specialism - Italian Clowns.

Twin, spaced-conductor stub lines, as used in impedance transformers, do radiate. Radiation can be significant specially at VHF and UHF where most of these transformers are used.

For not-so-wide conductor spacing radiation resistance is approximately -

20 * Square(S / Lambda) ohms,

where S is the conductor spacing. It tends to be independent of line length. Polarisation is in the plane of, and at right-angles to the conductors.

(As spacing increases beyond 1/10th wavelength the line begins to behave as a pair of parallel longwires. Radiation also occurs broadside to the line with lobes all over the shop.)

Loss due to radiation resistance degrades Q of the reactance (inductive or capacitive) which the stub is intended to simulate.

Short-circuit Xin = Zo * Tan(Theta) ohms

and Open-circuit Xin = minus Zo / Tan(Theta) ohms.

where Theta = 360 * Lambda degrees and Lamda = line length in wavelengths.

Which is simplicity itself until one attempts to take line loss into account. The Smith chart then falls flat on its face.

Another practical effect, nearer to home, is when a wide-spaced twin transmission line feeds the center of a half-wave dipole. The resonant frequency is still calculated from the distance between the dipole ends and not from the length of the wire. Radiation which no longer occurs from the gap in the center of the antenna wire is replaced by radiation from the feedline of just the right strength and polarisation.

Is this another example of radiation from a vacant space which carries no current ? So much for the old-wives' tales about radiation occurring mostly from the center of a dipole because that is where the greatest current flows. The system behaves as if the wire actually exists.

At VHF and UHF coaxial structures become more common. Being self-screening they radiate less and so have higher Q when incorprated in filters. Coaxial stubs have highest Q when inside a cylindrical can, sometines terminated with a trimmer capacitor. The name may be changed to receiver input tuned circuit. The inner conductor may even become a helix. But it's still a stub line!

Hi Mike,

During certain circumstances, the choice of wire position will invoke
a warning dialog window. This does not appear to be one of those
instances.

Cecil, you never told us you were in a chain gang. I thought Texas had abolished them years back. You have our undying admiration for your proven success on the design of no-tuner transmission lines achieved under such an arduous restriction.

By the way, what was your crime? And are you allowed to receive food parcels?

> a leaky loop stub is to model it.
==========
At last I think I'm getting the picture.

If that is what Art's invention is it is easily modelled.

If it's a dipole closely coupled to a largish square or rectangular loop then the coupling coefficient between the primary and secondary circuits can be calculated. The secondary cct is tuned. It's resonant. The primary circuit, the loop, is untuned. The primary and secondary currents, efficiency and other characteristics can be calculated.

From what I remember from previous threads broadening of bandwidth was the design objective. But there's no need to do any calculations - the bandwidth (Q) of a single tuned remains the same regardless of how the generator is coupled/matched to it.

Don't ask me quote a theorem.

Yeah, it was on 2 meters. This doesn't happen a lot like it did back 10
years ago, but it still happens, and it's always veteran hams that do it,
not no code techs or anyone recently licensed.

I've had two, a Novice 30 years ago, and one of them hated No code techs since 91, and I won't post them here, for various reasons. I'm sure you'll trash me, but I have good reason not to. But I did the 5 WPM CW thing already, and maybe I'll upgrade one of these days, but it doesn't have the draw it did ten years ago. Too bad...

So, in effect, you have never experienced anything beyond basic entry level operation? That's not much scope of experience to be basing such a negative view of the hobby on.

Since you claim to have passed the 5 WPM element in the past, all you have to do is show proof of it to the examiner when you take your General (or higher) written element and you will have your HF ticket. Isn't that what you wanted, elevated privileges without having to take the code test?

I just picked a Gap Callenger from an estate sale
for $50 (Canadian -- about 35 US). Because of
weather and other factors I have
not yet put it up, but the chap who ran it had a lot
of fun and many contacts with it. It does use radials,
but there are only 3 25 ft radials at the base, and
they can be laid out on the ground in most any fashion
(almost fractal!!!)

One of the biggest justifications for Ham radio licensing is
for emergency operations. It is MUCH MUCH more likely for
radiotelephone to be of immediate use (other than post-WWIII situations)
than code.

Code should be encouraged for those who like that medium, but
technical competency is much more important in general (esp for
high power operation.)

Lots of NCT's like fm simplex as much as the next guy. Some even use
other modes such as SSB, packet, and even CW. Why must the rudeness
only take place on repeaters? Have you never been to a club meeting
where it takes place in person?

> But basing you opinions on a very limited segment of the hobby (repeaters)

Your comments are very limited and misleading. I've heard noisy
elitists at the Dayton Hamvention where they don't care who they
offend.

Limited again. But a hotspot of rudeness. I witnessed a 2by2 with
the first name Curtis berating a new ham's first QSO on the air - on a
St Louis repeater. Apalling.

Sure, I used to be a ham... (probably before alot of these readers
where born.) Had the code and everything. Additionally,
the rules and regulations were easy... The technical part was trivial
(even as a highschooler, I didn't have to study that.) Sure, my First
Phone was a little more difficult, but still technically easy (the rules and regulations
were much more difficult.) I also had NO BENEFIT of tutoring, but
simply learn and understand very quickly (still do.) There is NO EXCUSE
for IRRESPONSIBLY avoiding the demand of technical competency,
because it is the tool used to support responsible behavior on the
shared airwaves.

Learning an anachronistic and rather less useful skill, like code is mostly
a waste of a newbies time (unless they *want* to use code.) For
typical emergency situations (nowadays), radiotelephone will be much
more useful. Trying to be elitist based upon an anachronism, has mostly
the effect of creating an exclusive club and creating a barrier in the wrong
place. If anything, the barrier MUST be on the basis of being able to
operate competently (including technical competency.)

It is good that code has been dropped on the above HF frequencies, but
even HF rules could stand some revisiting by the international organizations.

For those who claim that I might need to learn something, it would be
good to learn some respect for those who have 'been there, done that.' I
do have some problems with certain fine motor skills. The problem isnt'
any better since I was young. It isn't a handicap, but the anachronism
and simple waste of time for any operation that I would be interested in
is a serious disincentive (rather than the appropriate disincentive against
technical incompetency.)

It was good to hear that ham radio is starting to realize that they need
to look towards the future, rather than try to create a false elitism based

upon an anachronistic skill. If the elitism is based upon a currently (or future) strongly useful expertise, then there is some value. Ham radio does need to continue to self-police, but also appear to be friendly.

John

Good example: I wrote/re-wrote a significant amount of FreeBSD (the VM
code and other pieces.) Without knowing and being able to use assembly
or machine code, it would be a severe handicap for some groups of programmers.
However, there is usually an intimate relationship between machine code
and the code produced by high level languages. Understanding this relationship
and being able to exploit it can sometimes help to improve system performance.

Of course, technical knowhow, and the ability to solve communications
problems (e.g. interference, path loss issues, reliability), are MUCH MORE
important nowadays to render code to be a quaint curiosity.

I don't know where you've been, but there are people using assembly language today (2002). And it is for major companies, and leading edge products. Not all programming is Java and OO. Don't assume that one specific method of programming/language useless until you understand the reason for using it.

Also, don't assume that one method for transmission is inappropriate for all communications. Some operators prefer voice, some prefer code, that is their choice.

Code can be thought of as a requirement so that operators have sufficient breadth in their understanding of radio communication. Isn't testing about comprehension and proficiency. These result in the privilege to operate a radio.

(I wouldn't hire a programmer that doesn't know assembly.)

To me it is clear that code is a viable part of the hobby. When I no longer hear code in the HF bands, I may consider it to be obsolete. Since people are using it today (2002) it clearly isn't obsolete.

On the other hand arguing about this is rather pointless.

Later,

Craig

I'm far from a computer guru, but aren't all high level computer languages written in assembly/machine code? Aren't they all just basically interfaces between the processor (machine language) and the operator??

3050. Re: Grounding chimney mount antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-23 02:08:10 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <uttoohj9r4ds5d@corp.supernews.com>
Source record: 130782

In a previous life I used to install roof top TV antennas using guide 30
foot masts and we used about 1/8 inch diameter aluminum for a ground wire
with a small lightning arrestor on the twin lead. I saw many TV tuners
damaged by hits but that was the extent in addition to melting the sheathing
on the 300 ohm twinlead..

My own chimneys have been hit at least twice. First time in Denver with no
antenna but lightning found ground thru the sprinkler system and garbage
disposal, a 3 wire house built in 1979...I was at home at the time and
vividly recall hearing a hell of a loud bang and the smell of ozone...
The second time was Tulsa where the previous owner had a small TV antenna,
that I never used but one day I noticed that the twinlead had been fried,
but no electrical appliance was damaged, a 2 wire house built in 1949.. I
never saw any ground wire and perhaps the reason is that it got vaporized..
I've also had a large 50 year Pecan tree damaged, it's still alive but
missing about half its bark..
My advice is if your in an area with lightning then you better install a
substantial ground, as heavy wire as you can find, as short as possible but
allowing for gentle curves, no sharp bends. Don't depend on your house
ground because I've seen those where the connection was corroded and
lightning found another path. Wash a 10 foot ground rod in and leave enough
exposed for a good connection and inspection point. I doesn't hurt to use
some salt of copper sulfate in the ground rod hole to help the
conductivity..
Put a good lightning arrestor on the center conductor to your ground and
ground the braid as soon as practical...
And as super insurance get a GR quick disconnect and always disconnect your
eqpt, theonly really sure insurance. My Kenwood 850 got fried from a hit
to a ground mounted 18AVT that is surrounded by trees 3 times as high and
fed to the 850 thru 2 coax disconnects. My station ground must have been
too good.
good luck

|I recently started playing with EZNEC, and ran into a problem that
|should be easily solved, but I can't figure it out.
|
|When I take a 1/4 wave vertical over "real ground", with the lower end
|of the wire at the origin (in "ground", according to the wires list).,
|and raise it just a tiny fraction of a meter, it goes from nearly zero
|reactance to several thousand ohms. I assume that by raising the wire
|the source looses its grounding, so I tried creating a second (very
|small) wire with one end at the origin (in ground), and a transmission
|line between the top of that wire and the radiator. This gave the
|same high reactance.

If you take a quarter wavelength monopole operated against (perfect)
ground) you would expect (near) zero reactance and a real part around
30-35 ohm (assuming your source is placed on a segment very near the
ground end).

If you disconnect this from ground, then you have an end-fed quarter
wave radiator, which *will* exhibit very high reactance.

You must very carefully read about transmission line models. You
don't connect a TL *between* two wires, as you might envision
connecting a TL to the two halves of a dipole. You connect the TL to
a wire segment at each end of the TL.

Yes, this is pretty much how computer languages evolved. Assembly language is still used today mostly in the development of high level languages (C, VB, Java, etc.) and operating systems, because as each new processor hits the market, they have their own instruction set.

BTW, there is a difference between assembly and machine language. Machine language is that which is understood by the computer - the 1s and 0s. If you had to write and debug a program using only 1s and 0's, you'd soon become frustrated after trying to debug the first couple lines of code. Assembly is the next step up from machine language. It uses alphanumeric representations of the 1s and 0s that the computer uses, and a compilier converts them to the machine language that the computer understands.

Reminds me of a time when I was sent to Huntsville, Alabama to the Redstone Missile (also known as the Von Braun Hilton) complex for about a month. No matter where we went for breakfast, we got grits.

You could order pancakes and bacon and tell the waitress, "Hold the grits" and you still got the goddamn grits. Toast and coffee; you got a plate of grits on the side. So they tried to force you to eat grits but they would not let you buy a bottle of beer.

I think Alabama *was* a penal instution.

I think that is what I did (the latter example). I treated the
transmission line as a non radiating 50 ohm "wire" that attaches to
the end of the radiating wire (the vertical), and the end of a short
wire that is grounded.

Some one had better know how to write in assembly language. You do need to
develop ever advancing compilers etc and that may take some assembly
language programming even today.

A non-radiating transmission line can carry no common mode current. Therefore there won't be any current flowing to the ground due to connecting one terminal of one end of the transmission line to it. (Imagine if you will a coax tranmission line with a great bunch of ferrite beads along its outside.) If you connect only one terminal of a model transmission line end (that is, only one end of a short wire to which the transmission line end is connected), it doesn't make any difference what you connect it to or if you connect it to anything or not. (Same as a coax with a bunch of ferrite beads along the outside.) What you have is an open-ended stub connected to your antenna, but one that can't radiate. As far as the model is concerned, it's exactly the same as a lumped impdance (or "load") inserted in the antenna at that point. The impedance of the "load" is the impedance seen looking into an open circuited transmission line of the specified length and impedance. If you'd like, you can calculate the impedance you'd see looking into the line replace it with a load of that impedance -- you'll see no change in the results. You will, of course, see a difference between the stub and load if you change the frequency, since their impedances change differently from each other with frequency.

Roy Lewallen, W7EL

Ah, yes. But those of you who advocate "self-policing" are the very ones who
take it upon yourselves to sometimes play "net cop" while you titter and
tatter about the poor operating procedures of others. This is, in itself, a
form of elitism in that a minority of ops willingly choose to castigate
others for operating procedures with which they do not agree. Beware of
"self-policing" and the resultant criticism of other ops...this, in the eyes
of many, has not the appearance of being friendly.
So far it would appear that "self-policing" is but a nice feel-good idea
with little merit and zero results.

Machine code, and the textual representation of machine code: assembly language
are the lowest normal level of programming (ignore microcode, etc.) The
ultimate output of compilers and assemblers is the machine code. There are other
ways of making computers do what you want also, including 'interpreters' and/or
'emulators'.

One first creates a bunch of 'source files' that contain the program instructions
(in high level language or in assembly code), and then apply the source files to
a compile/linkage process, or directly execute the program using an 'interpreter'.
Interpreter programs can either 'execute' the code directly upon parsing (reading)
the program statements, or can create an internal version (or somewhere in
between.) In the case of compile/link-type systems, they produce a program that
can be run directly on the computer under specific operating systems that support
I/O and other functions. The simplest forms of Java are a hybrid, where you
compile the source files, but you run a program that interprets the psuedo-machine
code as if it is a real processor (well, sort of...)

There are more than I list, but off the top, I can think of at least these four methods
of 'making computers do what you want':

1) Compiler/Assembler/Linker:
These take a higher level language (assembler is slightly higher level than
machine code from a representational standpoint) than machine code, and
produce runnable machine code. This is like using Microsoft-C or MASM,
linking the output with libraries, and produce an EXE file for NT/2000. A
similar thing is normally done on Unix.

2) Traditional interpreter:
The MS Basic interpreter that Billy and friend wrote would directly execute
the text of a program, but reparsing and executing the code statement by statement.

3) Less traditional interpreter:
AFAIR, Perl creates a compiled copy of at least a part of the program, but the
'compiled' output is an internal representation that is used as a set of instructions
for software.

4) P-Code compiler/interpreter
Java and the old UCSD P-System on a PDP11 uses an explicit compiler to
produce a file that is similar to machine instructions. The difference is that the
'machine instructions' are actually created for a formally defined software

interpreter for those instructions. In some cases, Java performance has been improved so that during the 'interpretation' of those virtual instructions, native (real) machine code is made available for future execution in a given running of a program. Even further, it is possible to 'compile' those Java virtual machine instructions into an EXE-type file that would be normally directly created by a Microsoft-C or Unix-C compiler and linkage process.

So, I hope this helps to clarify, but probably is 'too much' from the standpoint starting from scratch.

John

I agree that there is at least one 'Barney Fife' in every organization. However, it is
better that Ham radio be self-policed than to have the FCC crack down only against
things that they politically don't like. If ham radio is allowed to be a cesspool of
people who violate conventions, but technically obey the law enough to stay under
the FCCs radar, then that would diminish the hobby. I am not familiar anymore with
the ARRL guidelines, but there should certainly be some guidelines so that the 'net-police'
or the
'ham-police' people who have a little too much zeal can be helped back to
more reasonable attitudes. The various conventions and rules of etiquette need to
be taken seriously, and I seem to remember that even when I got my license a long
time ago that there were such 'conventions.'

It is much better that reasonable guidelines be instituted, and strong suggestions
be made in the guidelines that the spectrum is to be shared amongst HROs
according to the law and conventions. If there aren't reasonable guidelines, and/or
intolerant people who seem to emotionally need to be snobs, then the self
policing will sometimes fail. Frankly, from what I have heard, the current scheme
seems to work okay, but there'll always be those people with too much zeal!!! :-(.

People do tend to be cliquish, and I have made various such mistakes in
previous situations. It is important that the 'elders' avoid become
condescending or turn into control freaks.

I don't mean to compare hams with other community radio service participants, but I remember my Dad talking about various groups believing that they 'own' certain CB channels (this was back in the 'Convoy' days). It is sadly odd, if not almost funny to think that someone is so diluded into thinking that they can have dominion over a resource like that. Again, times have probably changed a little on CB, and I am not making that complaint about amateur radio (I am just seriously thinking about ham again), but even good people can become petit and cliquish in situations that lend themselves to that kind of behavior.

I really believe in ham radio as a great hobby for kids of all ages (including those who are retired :-)). Computers are great (and I am a very serious computer person), but I'd like to see ham radio compete for alot of the mindshare directed towards the CREATIVE parts of the computer hobby... (I am NOT confusing the computer WWW addict with the real computer hobby of developing tools and applications that do interesting things.)

Hopefully, I'll have collected enough info in the next week or so to be able to embark on a new hobby...

John

You've found the key word...HOBBY. Its not a job or political position
and and if its a PITA you can (and should) just walk away and do
something else. No need to hang out on a repeater/club/band/newsgroup
if the general attitude there is such that aggravates you and takes away
from the enjoyment. No rocket science and no Morse code unless you want
it that way.
Good luck,
Bill WX4A

There was an article in the March '83 Issue of Ham Radio Magazine by K2ST
for a Precision Noise Bridge. If anyone can make a copy, I'd like one, too.

I do agree with that. It would be good if the unecessary cost of entry to HF
'Morse code' could be removed (limited by treaty) however.

My interest in technical competence for HROs is based upon being able to
responsibly deal with and understand problems dealing with more than low
power transmitters. With high power comes more responsibility for local
interference and occupation of spectrum space.

I don't see a problem with Ham radio having a pure communicator class
license, where there is little or no technical or code qualification. However,
that class of operators should be limited to purchased gear at low power on
VHF/UHF.

VHF/UHF seems to be the experimenter's playground these days and the intl treaty doesn't prevent >30MHz licensing without code. HF will be sticky forever. You can work around the world with a watt on HF, and so can the garbage spouting out of an improperly operated rig, so the potential remains for interference to commercial services and thats why the Treaty is such as it is. Its not an argument that I'm going to try to hold my own on, however. I recall that Japan went to a 'communicator' license scheme back in the 70s-80s and no-coders were given privileges up to 20 watts on HF or something like that. The bands didn't turn into a zoo-like cacophony of echoes and roger-beeps. Maybe in Japan it did...I wouldn't know.

>
> I don't see a problem with Ham radio having a pure communicator class

> VHF/UHF.

Well, with any drastic change like doing this on HF, there has to be some enforcement mechanism or else the existing rowdy ranks from 26-28 MHz have a real potential to screw things up for everybody on all bands. The FCC got out of the ham bizness many years ago when they turned over 'licensing' to the ARRL. The only time they even bother with enforcement of the Amateur Radio Service is when some nut goes berserk on 75 meters or a repeater and generates a ton of specific complaints. I don't think they want to go back to the patrolling mode like in the old days where if you said s**t on the air you'd automatically get an FCC notice (and a dozen ARRL OO notices)...and I don't think anybody wants to see that. But opening up HF would require such vigilence and we would all pay the price.

Bottom line is that- 1) 5 wpm ain't all that tough and 2) outsiders looking in to the amateur radio service don't necessarily have the same perspective of those already inside. Pity that it translates into a we vs. them scenario but thats human nature.

I've taught code classes with a hometown club and its very clear that some people simply can't master it but would be 'good' hams nonetheless. I'm not going to speculate about mental blocks and all that but I can

vouch for the ones that would jump up in the middle of a code-practice session and yell out "I ain't puttin' up with this s**t" and storm out of the room, yet 9-year-old kids were able to pass muster. I don't think they'd behave that way at the Driver's License office, so yeah, there's some level of committment that makes getting into the hobby something to work at, even if it may seem archaic. These same 'examples' are the same ones that will also piss and moan about putting their real name and address on a FCC License Application form.

There's a framework in place that allows most anybody whose knuckles don't drag the ground to get a ham radio license. The people who can't accomplish this...well, go figure.

> I don't have to do anything.

Wrong.
If you knew about DSP, you could easily hook up the radio to your laptop
and program, for instance, a scan mode that stops only on the "voice"
channels, and not simply where the signal is strong.
You could build your own noise-reducing filters.
You could get a programmable radio (Ten Tec?), and modify the firmware.

What you are saying is a bit like saying: Hey, I don't need to
know how to solder, my radio comes already soldered.

The fact is that more and more of the radio receiver functions in the
future will be done digitally. There are two main reasons:
it's more flexible, and it is easier and more repeatable
to manufacture digital ICs than analog ones.
In cell phones, in cordless phones, everywhere that radio
technology matters, digital is more and more used.
If you refuse to learn digital signal processing, pretty soon you will
understand about 5% of how a receiver works; the rest will be digital.
Of course, you will still be able to use code on archaic equipment,
but amateur radio should look forward, not backward.

3071. Re: EZNEC 3.0 Above Ground Vertical Question - Vert1 Above Ground.ez (0/1)

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-23 08:41:11 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <utufp8lapamsb4@corp.supernews.com>
Source record: 130803

Imagine that you have a 10.3 meter vertical wire with the bottom 0.5 meter above a copper-sheet ground. Then imagine that you have a very small, self contained and battery operated 40 meter transmitter. That's what the source represents. 0.515 meters above the bottom of the wire, you cut the wire and insert the tiny transmitter. Notice that the tranmitter has two terminals for the antenna -- one is connected to the 9.785 meters of wire above it, and the other is connected to the 0.515 meters of wire below it. Finally, imagine that you've got a 0.94 meter long piece of 50 ohm air dielectric coax loaded with ferrite beads along the outside of its whole length to prevent common mode current flow. You connect one end of this transmission line across your transmitter terminals, and let the other end hang, or connect one but only one of the conductors of the far end to ground. What impedance do you suppose the transmitter will see? Let's disconnect the transmission line for a moment so we can look at one thing at a time. Since one terminal of the transmitter is essentially open circuited (connected to a relatively short, 0.515 meter wire), you'd expect the transmitter to see quite a high impedance if the transmission line wasn't there. And, whaddaya know, EZNEC says the impedance would be around 3k ohms, capacitive (45.3 - j3293). Just what you should see. Well, what's the impedance of an open circuited, 0.94 meter long 50 ohm line at 7 MHz? about 0 - j360 ohms. That is, it looks like a capacitor. You put the -j360 ohms in parallel with the 45.3 - j3293 by reconnecting the transmission line to the transmitter, and what should you get? Pretty darn close to 0.42 - j314, which is what EZNEC reports. You can connect one conductor of the other end of the transmission line (in the model, one end of the short wire the end is connected to) to anything you'd like. As long as you leave the other conductor (or other end of the short wire in the model) open, it'll have no effect. In the real-life equivalent, the ferrite beads will prevent common mode current flow; in the model transmission line it's prevented by the way the line is mathematically implemented.

So you see, EZNEC has told you just what you asked it. You described an antenna to EZNEC and it told you how the antenna would behave. While it would be possible to create a modeling program that would try to guess what you want to do, and do that instead of what you tell it to do, it would certainly be unacceptable to anyone expecting it to do what it's told. I know that a program that would do that would end up in the trash here in a matter of milliseconds. And it would take that long only because of my declining reaction time.

I have no idea what you were trying to model, and neither does EZNEC. But we both can see what it is that you told EZNEC to model. And it did

tell you how the antenna you described to it would behave. To
successfully use any modeling program, you have to learn how to describe
to it the antenna you want to analyze. It can't -- and won't -- guess.

> either.

Thanks, Wes. That was it.

It seems to work OK now, except when I do the '3D' option I get an error about not finding the 'gnd.bmp' file, then it goes ahead and works anyway. I had moved the 4nec2 directory to the c:\ root. Now that I got it to work I will try moving it back to where I want it. I like to be able to organize my programs a bit, according to category.

There's a couple of other minor errors that come up, too, but I think they have something to do with not having some directory set up.

...and I am even mor impressed by the 3D pattern display, with color option. A bit more 'spit and polish' and 4NEC2X will be a real winner!

Richard the antenna has been one mishap after another.
My capacitor broke during assembly and I had to remake it.
On assembly of the center portion of the element the
capacitor drive belt keeps breaking because something
is sticking inside the element and it takes quite a while
to disassemble to try and resolve what happened. I will finish it
but I am beginning to question the need to do it, Hi.
Even thought of making the element a larger diameter than 1 1/2
but then that would be admitting defeat. Wife is getting
impatient tho regarding the neglect of her honey doo,s
and the chill of the comming winter has set in so I have
a real problem on my hands.When it is finally done I
will send you a photo

I hear you Roy and everything points exactly as you say
so it cannot be refuted.For myself I have difficulty in
comprehending what the 'radiation' losses are in actual numbers
i.e. the same or not the same to that when radiation is
not encumbered, but I shouldn't have deviated from what
is presently understood in the earlier post.

I agree that 5wpm isn't all that tough for many people, but learning technical
competency with a REAL technical exam would be a better allocation of time
for newbies. Exclusive clubs based upon anachronisms isn't helpful. Exclusive
clubs based upon competency, public service and even creating a larger
'technical' gene pool isn't a perfect thing, but much more socially justifiable than
'secret handshakes' like Morse code.

And that's like saying "I only want to learn what I want to learn for my license test, and that doesn't include Morse code, even though it is a requirement".

> The fact is that more and more of the radio receiver functions in the
> future will be done digitally.

Only *some* receivers. Generally built in factories by electronic professionals, not your average homebrewing ham. Yes, those receivers are marvelous. And demanding of advanced technical skills not found in the general amateur radio population, nor likely to be found there in the future where testing requirements don't demand such skill and knowledge. That's to be expected since only a small portion of hams are professionals who have that advanced training and skill. Far more are skilled at such "archaic" but very effective communications modes as radiotelegraphy. Many of those hams also are users of advanced digital modes, but few are trained in the development of those modes. Most are just happy to be users of them. That doesn't mean there are no technical skills among the general ham population. It DOES mean that technical skills among hams are far more likely to lie in other than the latest djgjtal technology. I don't see that changing as long as simple tests are all that are required for entry into ham radio.
While new hams who are serious about learning to engage in their newfound pursuits, few have the background to leap onto the digital design bandwagon. I believe fact that will forestall any great amount of digital design work by hams other than the smaller portion of the hobby who are already so engaged.

There are two main reasons:
> it's more flexible, and it is easier and more repeatable
> to manufacture digital ICs than analog ones.
> In cell phones, in cordless phones, everywhere that radio
> technology matters, digital is more and more used.

The operative term here is "used". Hams are more and more users of advanced technology and less and less designers. Most design by ordinary hams is at a level of technology below digital design using advanced ICs. I can't imagine why this should be surprising to anyone. Bu it always seems to bring forth dire predictions for the demise of the ARS

because of it. Won't happen. Our future is far more dependent on our emergency communications capabilities, and that demands little or no digital design skill.

> If you refuse to learn digital signal processing, pretty soon you will
> understand about 5% of how a receiver works; the rest will be digital.

Only the design of the newest receivers. Pure digital radio is still far in the future, save a niche element which is normal for advancement in the field. Analog radio is far from being ill, and very far from dying.

> Of course, you will still be able to use code on archaic equipment,
> but amateur radio should look forward, not backward.

That's your opinion, shared only by other similarly situated technical types. Most of us hams believe we should look both forward *and" backward. We have a great heritage and most of us won't forget where we came from and how we got here as we move into the future.

They are not and never have been our governing body. They are merely the
largest ORGNIZED group of amateurs. Thus we can have some clout in the
political arena and get heard by government policy makers.

Note that ARRL did not "take over" testing duties. There are many VECs
accepted by the FCC. All the VEC organizations have to meet with each other
on a regular basis and agree to each question pool, how often that pool is
changed, whether it is multiple choice, etc. If ARRL had "taken over,"
they would be in sole control of the testing. They are not. There is W%YI,
SANDARC, and a half a dozen or more other organizations.

But you speculated on what you should have researched for the incident actually under discussion. And it is improper to apply the happenings in the one city that you worked with to all cities. There are articles published by the ham magazines documenting the regular involvement with authorities during disasters of all types. Yes there are problem cities but there are others that welcome hams with open arms.

I was being sarcastic and trying to point out that the same argument can be used for anything that a person doesn't want to learn. Personally I happen to think that there should be more basics included in testing. For example, I think every ham should have to demonstrate that they can solder a connector to a coax successfully. However they don't have become soldering experts.

Bringing the coax lines into the house, and the trying to achieve
a true "ground" is going about things the wrong way.

The lines should be grounded before they
enter the house! Establish a ground panel at the entrance that is directly
tied to a ground rod at that point. You'll also need to bound the station
ground
rod to your electrical service entrance ground to meet codes.

If you have RF getting back into the shack, it's probably common mode
pickup on the shield which is radiating garbage back to the antenna
system. Try using common mode chokes (ferrite cores) on the coax
and rotor cables near where your ground rod and protection devices
are located.

Check Your Stats:

On a per capita basis, the ham radio community is shrinking and going nowhere. And on a per capita basis, Japan has twice as many ham radio operators as the United States.

The ham radio community is 50 years behind the times by holding on to this code thing.

The ham radio community has a very negative public image, so women and young people wouldn't take part in a hobby that's dominated by semingly bunch of old farts totally lacking in basic social skills.

Would you want to spend a Saturday evening having dinner with a ham radio operator?

I don't think so!

Hey guys, it is 2002, not 1952.

Antenna gain for a VHF vertical is directly related to the antenna length.
A
2-meter SuperStationmaster commercial vertical colinear antenna is
over 22 feet long, and has a rated gain of 4.8dBd on 146 MHz. Compare
that to the advertised gains for some of the amateur offerings... I'd
be very leary of any advertising claims, especially for a physically small
antenna.

That description of the Code fits the outsider viewpoint exactly. I'd
guess that more than half of the new 5 word-per-minuters cannot copy 5
wpm so there's hardly a secret society mentality. Last I remember the
code test was a multiple choice thing that doesn't even require solid copy.
So in some regards the code test is simply a 'trial by fire' and in
reality has been degraded so much as to be moot.
In the meantime, if int'l law says it must be done that way then I guess
one has to comply until it changes if you want to get on HF.

|
|Thanks, Wes. That was it.
|
|It seems to work OK now, except when I do the '3D' option I get an
|error about not finding the 'gnd.bmp' file, then it goes ahead and
|works anyway. I had moved the 4nec2 directory to the c:\ root. Now
|that I got it to work I will try moving it back to where I want it. I
|like to be able to organize my programs a bit, according to category.

Me too. I have all of my antenna programs in C:\AntennaModeling
(surprise) and by fiddling with the .ini file I have most everything
working. The exception is using ICECAP where everytime I try
something 4nec2 can't find some subdirectory or another. I just keep
adding directories as the errors pop up. Sooner or later, I'll have
them all <g>.

|
|There's a couple of other minor errors that come up, too, but I think
|they have something to do with not having some directory set up.
|
|...and I am even mor impressed by the 3D pattern display, with color
|option. A bit more 'spit and polish' and 4NEC2X will be a real
|winner!

Getting 3D to work on my machine was a real bitch. Arie and I worked
back and forth a lot and I finally found a new driver for my video
card. It works flawlessly now, except the driver isn't "XP approved"
and automatic powering down of the monitor hangs up. Such is Windoz I
guess.

Just for the record, Bill, the code test was changed to fill-in the blank.

As a new ham (licenses 13 months -- I sat for all 4 elements at once), my feelings re CW requirements are mixed. It is certainly a key part of the history of radio and our hobby. It is certainly a valid communications mode. My objection to the 5 wpm is that it is basically neither fish nor fowl. Studying to pass a 5 wpm receive only test is not the way to learn code. A valid agreement can be made, in fact, that it is exactly the wrong way to learn code. (At 5 wpm receive only, the best way to pass the test as quickly as possible for many people is to "see" the di dahs in one's mind and translate character by character. If there is a worse way to learn code in a way that building receive speed and learning to send, I can not think of it.

Purely theoretically (treaties and such aside), I would have little problem with a send/receive test at a reasonable minimum speed (10 or the mystical 13 wpm) or eliminating the CW test completely. As currently constituted, the U.S CW test results, I think, in REDUCING interest in learning CW.

Regarding the written tests...
It would help if the VEC group found an educator to review the tests. I haven't looked at the new Extra question pool, but the old one would never pass mustard as a beginning Ed. course Too many of the wrong answers are clearly wrong merely by reading them without any knowledge of radio theory or regulations. Too many of the right answers have an easily memorized pattern. Please note that this is comment in no way addresses WHAT subjects should be in the test nor to what depth - merely a comment on the quality of the questions. That said, I do recognize that writing "good" multiple guess questions is extremely difficult.

Finally (for anyone bored enough to read this far), by far the most difficult task I faced in becoming a ham was learning to solder 259s. One aspect of voice communications I have yet to learn (more accurately "have not been willing to learn") is referring to my self in the first person plural as in "We have been licensed since 19xx and we feed our XX with a YY."

In the early days this was true, but not very much anymore.

Once you have a "high level language" compiler, you can write the next
version in the compiler language; these days mostly C.

Simple example; the GNU C and C++ compilers have been written in C and
C++ for many years now as have most compilers and operating systems.

While assembly is still used somewhat, it is nowhere as pervasive as it
once was.

> which confirm that advantage?

Well at odd times I have said most of the following
but here goes. My antenna does work on all frequencies
but it only half of a success because those that know better
says it can't, so if I do get on the radio sometime again
I must be careful to not explain the antenna for fear
of being called a liar.
On my past work I found that in some cases (frequencies) my
single element showed evidence of some front to back which
my modeling also confirmed.
This anomoly occurred from the two main loop sides which
are huge factors when going towards top band.It seemed that
one side of the loop did not always radiate
at the same phase and thus created small front to back.
When I use the new form I am hoping for more consistency in
the radiation footprint ala consistency.
In former designs especially those with more than one element
the capacitors were in the boom which ofcourse is a larger diameter.
Because this side of the loop was at right angles to the
radiating elements the characteristic I am talking about was not
evident but at the time I was concentrating more on using one motor
to operate ALL elements. I have possibly over estimated my abilities
to place all inside the smaller element with special attention
to weight but for every setback I have made two strides forward so
all is not lost tho I may be replaced as a husband if I don't get
a success soon. Seems like Cecil and I are in the same boat regarding
work levels.

From the Quaker Grits FAQ.
Grits are made from the milling of corn kernels. The first step in the process is to clean the kernels; then, the grains are steamed for a short time to loosen the tough outer hull. The grain kernel is split, which removes the hull and germ, leaving the broken endosperm. Heavy steel rollers break up the endosperm into granules, which are separated by a screening process. The large-size granules are the grits; the smaller ones become cornmeal and corn flour.
++++++++++++

It could be Girls Raised in the South :-)

They have much the same effect in the South as Viagra, but only if you are from the Southern United States :-)

All Hail Bush!

You come close to that Right-Whine about guns. We here in the Pacific NW are particularly close on that issue too. Especially when the DC area snipers were traced back here to where they stole that gun.

From one store alone, the source of the sniper's rifle, more than 300 guns were stolen THIS YEAR! And that is up from about 250 FOR LAST YEAR! Responsibility and the Conservatives seem alien counter cultures.

The friend of the store owner expressed amazement at how the sniper got the rifle. To his estimation, the owner was on the ball and closely managed access and sales lest some miscreant arm himself through this honest dealer. With the yearly average of losing one weapon a day out the door - this is the best we can expect? Anyone who is on the ball, is not losing a profit when that gun goes out the

door - "stolen" or otherwise. I've heard that gutless refrain of "only thieves will have guns" till my ears bleed; I'm in no mood to listen to it again when it only takes a wink and a nod to step around the system. A "thief" doesn't need to rob anyone for a new gun. And the enforcement side of this? Gutted by budget cuts and emasculated through diluted rules, Conservatives had this hog-tied and ignored the booming back door trade. The Right-Whiners don't have the guts to put the shop owner against the wall with the snipers and let them count lead. And I don't want to hear that soap opera "How it's Clinton's Fault." Conservatives yowling that like rutting cats in the night don't catch mice.

When Bush spoke that to take care of Saddam, it would only take "one bullet," he exposed just how easily he could shrug off those same single rounds bringing down civilians. I wondered how he must've restrained himself from telling us that sniper's have constitutional rights too. To his credit he held back - lest he look like another sniper-hugger. Our security is going to hell in a hand basket and the politicians are having a field day creating one more department and padding their pay.

Of course, "this will take some time."

However, you have had nothing to say about the HAARP applications towards the coming war. Myself, I would be supremely interested in Amateur HAARP and making my contribution to the war effort. Also, I would like to see Amateur RADAR as a acceptable mode of operation. I still find fascination in "igniting large sections of the atmosphere."

death to terrorists!

Exactly. Why should I have to learn about UHF techniques to operate
HF? Why should I have to learn the VE rules if I'm not going to be a
VE?

> Personally I happen
> to think that there should be more basics included in testing.

Actually, all of the testing now is the basics!

> For example,
> I think every ham should have to demonstrate that they can solder a
> connector to a coax successfully. However they don't have become soldering
> experts.

We've been this route before, but here goes:

First off, you'd have to define "coax" and "connector". Think of all
the variations, from RG-174 to Heliax, from SMA connectors to type N.
Would soldering RG-58 to an RCA phono plug be sufficient?

Who judges the quality of the job?

What about those who are physically impaired to the extent that
soldering is impossible or very difficult?

You'd have to deal with those who would point to the wide availability
of crimp-on connectors and automated assembly. They'd say that manual
soldering is an anachronism. Heck, the UHF connector has been around
for more than 55 years!

It's possible to assemble an entire amateur radio station without coax
or soldered connectors, too.

Most of all: Our licenses are for operating, not building or
soldering.

Source record: 130744

Thanks for the explanation, Roy. I think I've got it now.

My first problem was that I missed the part in the help file about the transmission line only supporting equal and opposite currents, and what I tried to do was force the transmission line to work as a thing with 2 independent conductors. I also misunderstood how the transmission line would connect to a source. From what I understand now, each line will automatically connect to the corresponding terminal of a source, and support equal and opposite currents. In effect, since an ideal transmission line would not radiate, it follows that the same ideal transmission line would only carry fields that cancel out (ie. equal and opposite).

My second problem was that I tried to model a situation that could not physically happen in the real world. Consistent with the "garbage in, garbage out" principle, I shouldn't expect real world answers to an unreal situation. However, EZNEC did an admirable job producing meaningful results. It's just that I didn't understand what it was telling me (until now).

Thanks again.

==========

Tom,
Do you use Smith charts to design/analyse transformers with high impedance ratios where line loss can have a significant effect on line dimensions? I would have thought the complexity was well beyond Smith chart capabilies although I admit never to have used one in anger. There is, of course, the inevitable Smith chart error which assumes Zo to be purely resistive.

I have a program which does the same job as STUMATCH but with a lot more thrown in. It uses exact classical trans-line calculations to take line loss fully into account. But it is much more complicated to use because line dimensions and frequency must be included in the input data. I havn't put it my website because its complexity detracts from its usefulness for the majority of stub and similar -line designers of which I assume there are not very many anyway. From what you say I will tidy it up and put it on the website.

From a line constuction point of view, how close an approximation to working line length is acheived by adding to the computed length half the conductor spacing ? c/c, o/c ?

Reg, G4FGQ

> times by holding on to this code thing.

Agree 100% if you are talking about the code TEST.
I have no problem with anyone wanting to use code as
a choosen mode.

> The ham radio community has a very negative public image, so women
> and young people wouldn't take part in a hobby that's dominated by
> semingly bunch of old farts totally lacking in basic social skills.

Actually, I think the ham radio community has almost NO
image at all in the minds and perceptions of most people.

> Would you want to spend a Saturday evening having dinner with a
> ham radio operator?

Sure. Hams are, for the most part, normal people like
everyone else. Are there extremists? Sure, but every hobby
has its extremists...be it antique cars, model trains,
or whatever.

> I don't think so!

Why not?

> Hey guys, it is 2002, not 1952.

Agreed....

Cheers,
Bill K2UNK

You would be just fine with a short (about a foot)
"pigtail" of RG-213 cable having a male N connector
on one end and a male BNC on the other. Get an
experienced technician to make it up for you. It
will not have any greater loss than an adapter.

Do not modify the radio. It simply isn't needed.
BNC connectors are OK up to several GHz.

I am assuming that you misstated the connector
on your scanner - that it actually has a female
BNC connector on it. I haven't seen any scanners
that accept a female BNC (ie: there is a male
connector on the radio).

Good luck!

Make that good-quality RG-58 or RG-8X rather than
RG-213. I was thinking UHF connector, not BNC.

Hello to all.
I am looking for a vertical 6m design for fm work. The application will be for ARES operations. I need a design with no radials, as it may be used in an area where radials would be cumbersome in setting up. I already use hamsticks with a homebrew copper "mounting hub" for groundplane configurations on some home stations. These seem to work fine. In some potential shelter support operations, a design with no radials would be easier to deploy in the shelter area. I've started looking into the idea of half wave gamma loop fed verticals. I recently have seen a Q-Stick antenna which looked to use this method. I wouldn't mind building something similar. It would also make a great construction project for my ARES group. I was not able to look at the inside of the Q-stick, but assume it's similar to a regular "Ringo" design. I'm looking to see if anyone has any info about how this antenna is constructed(is there also a cap./or coil involved?) or if they have any other 6m gamma loop fed vertical designs to share. I'm also particularly interested in the gamma loop feed and how its circum/spacing is determined. Thanks in advance to all who respond. My best wishes for a safe and happy Holiday Season to all.

Frank:

A "J" is a half wave radiator with no radials. Many designs are around, incuding some using twinlead that you can hang from a tree or other convenient support.

An aluminum tube J was my first 6 meter antenna many years ago and it worked quite well, both on local contacts and DX when the band was open. I have used them on several other bands as well.

Grits, grits... did someone say grits!

Hey I lived in Huntsville, AL for 5 years, and I never ate grits.

Of course when I ate out, I usually ate at the "Ol Heidelberg" with the
rest of the "rocket scientists",
where I ate bratworst, and drank Spaten ale along with other Bavaian
delights.

Heh, heh... if you have only visited Huntsville for a few days or even a
month as Tom indicated he had,
why then you have not really sampled Huntsville's many charms. Located at
the southern extremity of
the Appalachan mountains in a verdant valley along the beautiful Tennessee
River, Huntsville, AL is a
wonderful town with more Ph.D's per square mile than any other place in
America.

The US Space and Rocket Center is located there, along with the Redstone
Arsenal, the Marshall Space Flight Center,
and most of America's premiere aerospace companies. It has two
Universities, and many interesting commercial
companies, such as the world's greatest xDSL company, Adtran, Inc,. the
third largest software company in the
country, Intergraph, to whom Intel pays royalty homage, as well as many
others... such as the "inventor's" of
ultra wideband radio systems, etc... etc...

Each year in August, they host one of Americals premiere hamfests, the
Huntsville hamfest.

In addition Huntsville is the ice hockey capital of the American South, with
two league leading teams, one semi-pro
and one Division one NCAAU college team, the UAH "Chargers", playing each
winter at the Von Braun Civic Center arena.

The Huntsville Amateur Radio Club usually sweeps the annual Field Day
contest with their high energy entries.

What more could you ask, all that and grits too?

knowing assembly makes you a better HLL programmer. a few years ago there was an online "contest" among friends to see who could write the tightest yahoo chat client. i wrote four clients... using compiler BASIC (one allowing inline assembly), C, C++, and MASM. many of the "C-only" guys [you know, the ones who constantly quote the ANSI (or ISO) C standards like they're the constitution] who bragged about how efficient C compilers were and how obsolete assembler is... could not put out tight code. the guy who put out a really nice C client understood both the hardware and how his compiler (VC++) worked. you can learn a lot by using a disassembler on the compiler's output.

i've heard all the excuses of why not to learn assembly: "assembly is not portable"... well do you plan on porting your code? code is often intimately tied to the gui and OSes API (ok POSIX). "it doesn't matter because we have a 2 GHz CPU"... fine, then go use VB instead... and that is exactly what is happening. why? because 80% of boxes run windows and people want it done yesterday. IMO learning C is easy compared to grasping the win32 api.

i like procedural over OOP because it approximates the hardware better... i prefer Dennis to Bjarne and both to Anders. Gosling and Meyer... don't even ask lol. Kemeny and his contribution were brilliant... he wasn't Einstein's math assistant for nothing... i have one BASIC compiler that is quite good. Craig is right: all languages have their place (of course that place might be the trash can j/k). C is very popular (try to find a haskell compiler for a PIC MCU) but for me it's a love/hate thing because assembler was my first language. Java is always being pushed and while it makes sense for some stuff (Servlets/JSP) it's a dog for general apps.

Jim, N2EY wrote perhaps the most cogent statement of this thread:
"Our licenses are for operating, not building or soldering."

Anybody may solder. Only licensed operators legally send radio signals
where licenses are required.

Avoidance of interference and minimum regulation are FCC goals. I
applaud their aim and wish they could go farther, faster.

Ability to "roll your own" has little to do with avoiding interference.
Knowing the rules and how to comply needs demonstration for a license.
You don`t need to know radio construction to be a good ham.

You should have something interesting to ask or say once in awhile.
There`s plenty of "rig here is blah, blah, blah." A variety of interests
adds spice to life.

Best regards, Richard Harrison, KB5WZI

Great!

>
> If that is what Art's invention is it is easily modelled.

Correct. As long as the loop is coupled along side the dipole
but not when the loop enters the dipole.

>
> If it's a dipole closely coupled to a largish square or rectangular loop
> then the coupling coefficient between the primary and secondary circuits can
> be calculated.

Correct

>he secondary cct is tuned. It's resonant. The primary
> circuit, the loop, is untuned.

Stop!
If the dipole is the part that is fed then that is
the primary circuit not the loop which tho 'tuned'
by varying the capacitor must be termed the secondary circuit.

>The primary and secondary currents,
> efficiency and other characteristics can be calculated.

Correct, but it appears that some programs or operators are
unable to perform, since it requires the use of a constant impedance
instead of a lumped capacitive constant (pF) to obtain the correct
design. I use the AO program by Beasely which is quite old but
still predicts accurate results tho not acceptable to some.

>
> From what I remember from previous threads broadening of bandwidth was the
> design objective.

No! That was another design(Capacitive coupled element feed).
This design as an assembly (primary and secondary circuits) can be
used on any frequency. An analogy could be that we have two
frequencies that are mixed to make another frequency, by changing one
frequency the final value changes.

Of course we do know that the loop is nothing but a stub where the
radiation does not cancel itself and does provide a means of matching
as well as
providing a phase change at the center of the dipole. No matter what
the frequency used the current or radiation 'lobes' (note that the
word is plural)
of the dipole are always in phase.
Where Cecil provides the match point at the end of a transmission
line stub
mine is always at the antenna feed point. I don't have to mess with
different lengths of transmission lines or equivalents if and when I
change my frequency.
This is not meant as a slap against Cecil's aproach where the
interests are for "BANDS" where-as mine is for ALL frequencies.

>But there's no need to do any calculations - the
> bandwidth (Q) of a single tuned remains the same regardless of how the
> generator is coupled/matched to it.
>
> Don't ask me quote a theorem.

I don't mind hearing of a theorem I just want to know if it applies to
my design which is not meant for 'broadening' bandwidth but for
frequency dexterity. Of course all this doesn't really matter since it
can't
possibly work as I stated. Right?

When I get on the air with the latest form I will be silent
regarding what antenna I am using as it has not been approved.
I do not wish to take the chance of being deported or burned at a
stake
at the next ARRL Hamfest where all will be allowed to throw stones.
I still have a Cockney accent, do you think it will show
if I only use code?

|why then you have not really sampled Huntsville's many charms. Located at
|the southern extremity of
|the Appalachan mountains in a verdant valley along the beautiful Tennessee
|River, Huntsville, AL is a
|wonderful town with more Ph.D's per square mile than any other place in
|America.

Now that is hardly a recommendation.

I think it was about 1973 when I spent my time there. We were
installing the instrumentation and launchers for the TOW Missile
"Fly-to-Buy" test range.

There was a former NASA, then a Hughes QC guy who was a local boy who
took us under his wing and showed us the sights. One sight was the
rundown farm his brother owned. Most of the conversation consisted of
his brother bitching about how there was no way to run a farm without
any Negroes (he used a less politically-correct term).

As a young man who grew up in Tucson where there were few blacks (but
a lot of Mexicans) I was shocked to sit in eateries and listen to the
talk around me. All I could think of was that I was glad I wasn't
black and living in that place. Former Nazis of course had it made. I
figured that if it had been determined that the Earth needed an enema,
they should inject it at Huntville, Alabama.

|
|The US Space and Rocket Center is located there, along with the Redstone
|Arsenal, the Marshall Space Flight Center,
|and most of America's premiere aerospace companies. It has two

|Universities, and many interesting commercial
|companies, such as the world's greatest xDSL company, Adtran, Inc,. the
|third largest software company in the
|country, Intergraph, to whom Intel pays royalty homage, as well as many
|others... such as the "inventor's" of
|ultra wideband radio systems, etc... etc...
|
|Each year in August, they host one of Americals premiere hamfests, the
|Huntsville hamfest.
|
|In addition Huntsville is the ice hockey capital of the American South, with
|two league leading teams, one semi-pro
|and one Division one NCAAU college team, the UAH "Chargers", playing each
|winter at the Von Braun Civic Center arena.
|
|The Huntsville Amateur Radio Club usually sweeps the annual Field Day
|contest with their high energy entries.
|
|What more could you ask, all that and grits too?

Yeah, but will they let you buy a drink in a bar without having to
join a "private club?"

> ---
> Reg
[snip]

No Reg... I really meant America, i.e. includes, Greenland, Canada, USA,
Mexico, Belize, etc... all the way down to
Patagonia and Tierra del Fuego.

And... Huntsville is not really an academic place filled with bookish
Ph.D.'s , heh, heh... These Ph.D.'s do *real stuff*
they are rocket, explosive, projectile, chemical, etc... specialists. They
have *big* labs and make *lots* of noise.

You will note this especially because often you are startled by the whole
Tennessee Valley rocking and rattling as the
Ph.D. rocket scientists fire off those big rocket engines on the test stands
at the Redstone Arsenal over by the
Tennessee River.

Or, for less constrained real excitement... since after Tulsa, OK,
Huntsville, AL is rated second on the list of US cities as
ordered by number of direct tornado strikes, you can *enjoy* the excitement
of "air raid" sirens going off, at various times
of the day and night, whenever lines of severe weather ["severe" in *tornado
alley* means heavy thunderstorms, rain, hail
and likely tornados] approach, which happens often in the early spring and
late fall. A handful of good folks were killed
over in Carbon Hill, AL just a few miles from Huntsville, only last week.

For *quiet* fun, you can go down to the Tennesse River and catch some really
big bass, hunt for Indian arrowheads
along the shore, or in the fall you can watch the local farmers pick cotton

out of their red colored cotton fields along
the river side using their huge mobile cotton picking machines.

Rocket Scientists and Cotton Farmers, that's Huntsville, AL. Me? I liked
living in Huntsville. Huntsville, AL which
is known as "Rocket City, USA" and as Wes noted on his short visit... they
do serve grits and hominy if you want em.

But... I like it better here in East Central Florida where, since I'm
located just a few miles south of The Cape out here
on the barrier island, I can watch the *big* rockets arch up over the palm
trees from my own backyard as they surge
upwards into orbit on their firey plumes. In fact I did so this evening
while toasting the Endeavour shuttle launch with
a glass of wine while sitting out by the pool under the full moon.

Solving problems and knowing when the problems happen is important
to being a good ham or anyone else who uses the shared EM spectrum.

It is basic to any owner/operator of a transmitter (when you don't have
a technical support staff) to be able to deal with the responsibilities of
potentially interfering with other people's activities. Being able to solder
coax to a connector is important, if the predominant technology for
connecting a transmitter to a feedline or antenna is purchased seperately
and mix/matched (or hopefully built) by the operator.

There currently is ALOT of EM irresponsibility (at least in my town of
Indianapolis), and from my view, my current interference source isn't
from the HROs, but from organizations like the power company. So, there
are even unintentional transmitters. You don't even need a box called a 'transmitter'
to be a poor EM citizen.

Those who own/operate/maintain/powerup/connect their own transmitters
(esp high power units) (FOR EXAMPLE) need to understand the ramifications
of using zipcord for transmission line on 10meters. It'd also be good if they
understand the effects of dissimilar compounds when using even a moderate
power transmitter perhaps compounding the problem with poor matching in
a feedline system. It'd even be nice if HROs who assemble
their systems from components (e.g. antennas, coax, transmitter/receiver)
understand what 'matching' really means, and not get paranoid about a
1:1 SWR when they forget (or ignorant about) other factors like antenna
radiation efficiency, and the ability to cause the antenna to actually absorb
the signal (rather than make a superficially desirable impedance match
at the transmitter) being important. A 1:1 SWR into a resistor wouldn't
be very good for long distance communication, and not all antennas
are created equal.

We cannot fix the world by making sure that all HROs can quickly put together
a trap or a wide dynamic range preamp for difficult situations. We also cannot
fix the world by forcing people to avoid eating every meal from McDonalds
or excessively smoking cigarettes either. Change and growth will happen if
there is more of a carrot (e.g. the simple Ham EE being made more interesting
and helpful, rather than being treated like a bastard stepchild by the
communicator class of users), rather than a stick (creating an exclusive

club for the purpose of discrimination.) The stick approach (REQUIRING code for qualification) had already existant for too long, but that problem is apparently at least partially being mitigated!!!

John

Perhaps I didn't express myself clearly, for which I
apologise.

Suppose we are talking about a length of 16 gauge
1/2 in diam copper tubing which has been wound into a coil.

If the ends of the tube is open, it does not matter
if you connect the lead to the inner or the outer surface of
the tube.

If connected to the outer the current will flow
mostly on the outer surface and the current density across
the thickness of the wall will decrease roughly
logarithmically from the surface to a minimum value on the
inner surface of the tubing.

If connected to the inner surface the current path
will be towards the surface for a short distance, the
current distribution will be the same as the previous case.

The current does not go looking for a hole on the
tube to reach the outer surface.

Alan.

Any current attempting to penetrate into a conductor creates a field which, in turn, creates a current opposing the original field. The result is that the current decreases in an exponential manner from the surface downward. This is known as skin effect, and much more elaborate explanations can be found in any electromagnetics text. The net result is that at HF and higher, no appreciable current can flow through a good conductor of any reasonable thickness.

> the tube.

In practice that's true. In order to make a connection to the inside, you have to poke a wire inside the tube. Then you have a coaxial line inside the tube, which will support current flow on the inside. You'll end up with essentially the impedance of the short length of coax in series with the coil, since this is the path that the current on the inside will take to the outside. If you connect right at the end of the coil, the distance from inside to outside is short. But no significant current will flow on the inside beyond the connection.

> If connected to the outer the current will flow
> mostly on the outer surface and the current density across
> the thickness of the wall will decrease roughly
> logarithmically from the surface to a minimum value on the

No, the current density decreases exponentially with depth, not logarithmically. A logarithmic function changes very slowly, an exponential function very rapidly.

> If connected to the inner surface the current path
> will be towards the surface for a short distance, the
> current distribution will be the same as the previous case.

Any current on the inside or outside of the tube will decay very rapidly from the surface. I'm not familiar with tubing measurement, but _Reference Data for Radio Engineers_ says that sheet metal gauge usually refers to B&S, and 16 gauge is 0.051 inches thick. Let's use that for an example, and say that the tubing wall is that thick, and copper. At 10 MHz, the skin depth in copper is about 0.00082 inches, so the wall is 62 skin depths thick. A current density of one amp/m at one surface will be e^-62 = 1.2 X 10^-27 amps/m, or .000000000000000000000000012 amps/m at the other surface. No detectable current will get through.

But no appreciable current will flow on the inside anyway, unless you put another conductor inside the tube. I've spent a while trying to come up with a good intuitive explanation of why this is, but haven't found a way to do it without prompting additional questions which require additional detailed explanations. The answer lies in Maxwell's equations, particularly Ampere's law, but I'm not up to hitting that tar baby. If you simply want additional support for this, find any text or handbook that discusses waveguides, and notice the extreme attenuation of any wave traveling inside a waveguide much smaller than about a half wavelength across.

> The current does not go looking for a hole on the
> tube to reach the outer surface.

You can bet your coulombs it does. Good thing, too, or our coax, screen rooms, and shields would leak like sieves.

Interference from radio radio use is all that regulation need address including hazard to people and property resulting from radio operation.

I don`t care if an operator wastes some 10-meter energy in zipcord if it doesn`t raise my insurance rates. If he weren`t wasting power in a zipcord he might be out on the steets wasting more energy as fuel.

The best jockey may not be a veterinarian. The best driver may not be a mechanic. And, the best radio operator may not be a technician.

In the days when little was known of the utilization of mysterious electrical forces, it made some sense for regulation to be restrictive. That era is long past.

The twisted-pair wiring used in networking is supposed to be
significantly different from that used for doorbells.

When I built my house in 1986, I ran three twisted-pair shielded
communications wiring all over, mainly for 9600 baud peripheral access
via RS-232. I was thrilled in 1997 to learn that networks coukd be
run on twisted pair. I was less thrilled to learn that the twisted
pair used for networking was nothing like my twisted pair.
Apparently, the new stuff can handle 100 MHz because that is what the
networks run at. Unless attenuation is very high, HF should be no
problem at all.

Roy I still cannot go along with your aproach (don't want to appear insolent)You dwell on 'distance ' and 'holes' instead of impedance paths.
A 'hole' encumberes the flow or escape of radiation when its size is small
compared to the wave length, minute holes in coax is thus useful(OK) for high frequency but certainly not for VHF and above where it can 'leak like a sieve'.
On the other hand a wire carrying RF WILL allow entrance thru a small hole
because it is now the best impedance path (I see this as a suppression of radiation in a confined space) If you didn't use the term 'distance"
in the first place all this discussion would be moot.
Another point I wish to make is that the 'skin depth'term is being misused.
I often use thin aluminum foil for antennas used for top band, this may only be the 'skin depth' thickness suggesting that it cannot carry all that is imposed on it, which is not true. Skin depth has a relavence to the THICKNESS of the material being used and thus is not a 'constant'.

Twisted pair telephone wire tends to have an impedance of 100 - 120 ohms at HF. I have use it at 1.08 MHz and 1.544 MHz. Don't remember the loss, but a stab in the dark would be 30 db/mile at those frequencies.

From: Bill Ogden <wogden@attglobal.net>
Message-ID: <3de11776_2@news1.prserv.net>
Source record: 130700

I briefly talked with the Alpha-Delta about using one of their half-slopers on my current 40' tower, were I considered placing it at about the 30' level (so as not to interfere with the quad). They said there was not enough counterpoise above it, since the quad presenting much less top loading than a typical tribander.

Since they talked themselves out of a sale, I assume they had good reason for what they said about the need for some amount of loading above the half-sloper feed point. Whatever one might think about purchasing a half-sloper (as opposed to simply creating your own), the AD people do sell a considerable number of these and need to deal with many users. Their experience appears to be that substantial loading (whatever that might mean in quantative terms) above the feed point is needed in order to produce predictable loading.

Hence my question about my soon-to-be new tower. I would have more tower above the feed point than when I asked AD about my old tower.

I have one for 10 and 6 meters. There are detailed plans for that antenna in the "Orange paparback" Bill Orr antenna handbook. But there is not much to it.
The loop on my 10m version is about 9 inches dia. The cap used is about 50 pf. These are made from coax. "Yes, I think qualifies as a stub". So it's easy to caculate for other bands. IE: 6m, use about a 4-5 inch loop. Probably about a 15-25 pf coax cap. You might want to look at the cushcraft web site. They have PDF files of the manuals for their ringos. You can use them for ideas also. These antennas are easier to build and set up/tune than they look. I've never had a problem getting a good match. And the antennas work pretty well. MK

Art, KB9MZ wrote:
"Richard knows I have a collection of books---."

Thank you for kind words.

The smaller the hole an r-f carrying conductor passes through, the more opposition it presents to the r-f. Current induced in the surface surrounding the hole opposes the r-f according to Lenz. The entrance/exit hole needs to be large to keep opposition small. Remember the chassis holes for I-F cans? Also, use the same hole for entrance and exit. Separate holes double the opposition as each opposes the same current coming and going. Also, coming and going currents in close proximity tend to neutralize each other reducing opposition to current wired through a shield. R-F tends to take the path of least inductance when the resistance is low. The coming and going paths need to be kept close together.

Hole size and placement are not simple parameters in many cases. But, Roy has the skin effect information right.

Best regards, Richard Harrison, KB5WZI

Hi Ken,

You have to be careful in that not all characteristics are fungible between RF and digital. For one, a digital signal is 1's and 0's and as long as there is sufficient S+N/N ratio (roughly 12dB or better), a lossy cable is not that much a problem. The problem for digital (and not necessarily RF, or at least not at this scale) is dispersion (phase integrity). That is the number one killer. Even then, some years ago I noticed that in-house routers rarely could manage more than 30M in distance from a hub to a terminal.

When it comes to assessing loss, you need only look at the gauge of the smallest wire. How does it compare to good RF Power transmission line?

A related topic:

I remember reading somewhere that shielding is not perfectly effective.

By way of an example, if you had a random wire antenna (with perhaps 1kw for example) installed only a few inches away from a thin alumuinum sheet (perhaps 0.125" thick), the RF will excite currents in the aluminum sheet and those currents will run sufficiently deep that RF will "leak through" to some degree to the other side. I would assume that, for the random wire, the current node (0.25 lambda antenna length) would be worse than the voltage node (0.5 lambda). I saw a table that provided attenuation factors (dB) for various thicknesses of various metals at various frequencies.

Do I understand this correctly ?

Hi Bill,

The tower and quad present an opportunistic radiator for some
characteristic frequency. I think we can all agree it is unlikely to
fall into a ham band. Outside of that frequency, and with sights set
on 80/160, we must resort to matching - enter the half-sloper pressed
into out-of-band service.

The discussion of application at 80/160 must then turn back to that
opportunistic radiator as we ask the question: is it tall enough? The
tower height gives some clue. A 50' tower would be quarterwave at
60M. 80M would seem near, and 160M a long shot. Consider how small
radiators are made longer with top-hats. The question the AD people
had with what you were mounting, was to assess the quality of top-hat
action.

In their estimation, your quad does not have the same coverage and
continuity as does a yagi with boom grounded elements (which is
probably at the top of their assess). This answers the significance
of counterpoise/mass. However, given just an empty boom swinging in
the wind, that is enough to boost the tower's effective height into

80M class as long as you have some radials. At that point I would simply abandon the half-sloper and build two gamma matches into the tower. I can see several advantages: less feedline, and an optimal match at the antenna (rather than through a swinging dipole). If you could insulate the base; then you would also have a half-wave 40M candidate.

Hi Jeff,

Richard has undoubtedly published those notes here at one time.
However, the observation:
>and those currents will run sufficiently deep that RF will "leak through" to
>some degree to the other side.
has been answered by Roy out 20 odd places. As you can appreciate we
do not live in a perfect world.... :-(

As for:
>I remember reading somewhere that shielding is not perfectly effective.
again a perfect world evades our lot.

Sometimes perfect is relative to the swing of the needle on a Simpson
260. Sometimes perfect is relative to the swing of the galvonometer
shadow.

No one is going to measure leakage alongside the cable with a Bird
Wattmeter. The cable is perfectly shielded - once again skin effect
proves out. Anyone is going to hear the leakage through the cable
with a handheld SW reciever. The cable leaks like a sieve and
demolishes the myth about skin effect.

The practical side of this is that if there were an announcement that
"Perfect" Transmission Line was available in your favorite style at
only a nickel a foot more - we would wait for it to show up on spool
ends in the telephone company repair yard.

Are you sure that you understand the issues of more effectively matching
and/or coupling to a junction of dissimilar conductive materials? This is not
just an issue of energy waste, but also of creation of spurious signals. The
problem is less trouble at lower powers, but I suggest that the problems are
more readily apparent at high power levels.

I don't advocate taking away access to 20-50W transmitters for the non-technical
communicator class of HROs. The problems caused by these devices are
often easily solved by ad-hoc tips and techniques.

Sure, there are issues of inefficient transmission (and leakage of RF into
neighboring apartments), but those are only the first order problems. Those
people ignoring these issues (or simply unknowledgeable) is one powerful
reason why ham radio needs an excellent technical education program.

John

(Normal) coax cable is a bad example because the shield is rated at 9X%
coverage.

The particular example I mentioned is a genuine question to anyone that
might have hands-on experience or applicable theory.

1kw into a random wire antenna. Bottom of the wire is mere inches away from
an aluminum panel. Directly behind the panel are low-level signal wires.
Is it surprising that the outside antenna might couple EMI onto the inside
wires even with the aluminum sheet between ?

Curiously yours,
Jeff

Hi Anad,

So we are designing a coplanar patch antenna for 1800/2400 MHz with
similar behavior (by that I presume you mean its radiation pattern and
load).

As for the "I tried couple of things like placing another slot inside
a slot" is difficult without an image. Please post an URL (do not
send to this forum) for a graphic of your design(s).

You haven't touched on what makes it interesting, nor have you
discussed what you have read.

Hi Jeff,

If it were only that simple. There are very, very, very few enclosed systems at work in the world today. Not even submarines. But if you were to simply place a wire mesh (not even solid, welded seam metal) around the object of interest, it would undoubtedly go fairly undisturbed through the current punch (let's cut to the chase with a mere KW) of a lightning bolt.

There are still ways into the enclosure because in real life there are real exits from the enclosure. And sure as there's little green apples, one of those leads contributes to shield failure. All it takes is making the wrong guess as to where ground is (almost like the Wheel of Fortune for this board).

Now, if you want to test an extreme, consider the HP608 line of Sig Gen.s. At -127dBm, its below cutoff waveguide attenuator (one of the best attenuators designed) might suffer more stray leakage at the attenuator's input than is lost through attenuation to the measuring device. In this case, the through the air source-to-detector loss was less than through the attenuator.

When you think about it in those terms, and when you consider that these systems do not employ shabby standards, and when you consider we are speaking about signal separations of 134dB over the stretch of a lab bench (1 or 2 meters); then practical shielding begins to show some scope.

Re TEMPEST: The ratio between 1 kw and a minimum usable signal is
something like 190 db. Making the usual assumption, the ratio of 1 A to
1.2x10^-27 A is over 500 db!
TEMPEST problems arise when other than solid shields are used and
when connections radiate. Mac N8TT

"Richard Clark" waxed poetically:
<snipped>

So - the nasty EMI is not going through the aluminum, but more likely going around. Thanks.

3184. Modeling a Wire Fence in EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-25 00:37:06 UTC

Message-ID: <ucr2uus14gmkhkbtsefesnatj6drcahmgp@4ax.com>
Source record: 130573

Having read the conventional wisdom that wire fences should be
grounded and used as additional counterpoise for ground plane
antennas, I decided to try to model this in EZNEC 3.0. I have the
regular version, so I'm limited to 500 segments. How can I make a
simplified model of a 4 foot high by 100 foot long section of 2x4 inch
wire mesh that is around 400 segments or less?

Thanks for any suggestions.

I think there is a misunderstanding here,I tried to use the term
'encumbered'
in what I was saying which is quite different from zero radiation. You
are suggesting that energy loss due to radiation is a constant no
matter how it is confined or what it is traveling thru,it is this
position of yours that I have trouble aligning with.

You're illustrating the difference between the philosopher or mathematician and the engineer. You see, a mathematician and an engineer were placed on one side of the field, with __________, the object of their sexual desires, on the other. (Use whatever name you think appropriate.) Each time they tried to approach __________, they were allowed to go only half the remaining distance.

The mathematician never got there. The engineer got close enough for practical purposes.

So let's see how "imperfect" 0.125" of aluminum would be for shielding. Shielding is more complex than just regarding skin depth, because you have to consider reflection of the wave at the interface between the metal and the air, the attenuation through the material, and if enough gets through to worry about, the reflection at the other side of the material. Being in the near field complicates matters, since the ratio of E to H fields aren't in a fixed ratio.

But we're taling about skin effect and skin depth here, so let's see what happens. A #12 wire spaced two inches away from a large plate will make a transmission line of 275 ohms characteristic impedance. If you're running 1 kW, the current on your wire will be sqrt(1000/275) =1.91 amps. Let's say 2 amps to make it easy. There'll be 2 amps flowing along the aluminum sheet under the wire. The concentration (current density) will be heaviest right under the wire, and decreasing to the sides.

The skin depth is greatest at the lowest frequency, so let's assume worst case of 1.8 MHz. At that frequency, the skin depth in aluminum is 0.0024 inches. So at 0.125", the plate is 52 skin depths thick. This means that the ratio of the current on the bottom to the current on the top is e^52 = 3.83 X 10^22 times. The current on the bottom side of the sheet would be 5.22 X 10^-23 amps, or 500 nano-pico amps. In terms of dB, the attenuation is 452 dB. Just how much is that? Well, if you put the total energy output of the sun into an attenuator that reduced it to the light output of a two-cell flashlight, the attenuator would have 280 dB of attenuation. We could attenuate the flashlight by that same factor again, then again by a factor of a billion, and still not have as much attenuation as that sheet of aluminum gives to that current at 1.8 MHz. Only a philosopher would conclude that some current gets through; no engineer would.
